ABSTRACT

The in-plane edge impact of composite plates, with or without a protection strip, is investigated in this work. A computational analysis based on the Fast Fourier Transform technique is presented. The particular application of the present method is in the understanding of the foreign object damage problem of composite fan blades. However, the method is completely general, and may be applied to the study of other stress wave propagation problems in a half space. Results indicate that for the protective strip to be effective in reducing impact stresses in the composite the thickness must be equal or greater than the impact contact dimension. Also large interface shear stresses at the strip - composite boundary can be induced under impact.

LIST OF FIGURES*

1. Geometry of in-plane edge impact of a composite plate with a protection strip.
2. Body wave speeds and Rayleigh wave speed versus fiber lay-up angle for 55% graphite fiber in epoxy matrix.
3. Branches and singular points in the complex Laplace plane.
4. Rayleigh wave for stress t_{11} , impact time 35 μ sec, impact length 2 cm, 55% graphite fiber/epoxy matrix 0° lay-up angle - no strip.
5. Rayleigh wave for stress t_{11} , impact time 35 μ /sec, impact length 2 cm, 55% graphite fiber/expoxy matrix 15° lay-up angle.
6. Level computer map in x_1 - time plane for applied stress t_{33} , 0° LAY-UP ANGLE on $x_3 = 0$.
7. Level computer map in x_1 - time plane for stress wave t_{11} , 0° Lay-up angle on $x_3 = 0$.
8. Decrease of impact stress with distance from the impact edge.
9. Stress t_{33} versus time for normalized depths $x_3 = 0, 1, 2$.
10. Maximum impact stress levels versus layup angles for 55% graphite fiber/epoxy matrix composite.
11. Effect of layup angle on distribution of stress t_{33} versus x_1 at a normalized depth $x_2 = 1$ for 55% graphite fiber/expoxy matrix composite.
- 12a Effect of steel edge strip thickness on impact stresses at the strip edge interface for 55% graphite fiber/epoxy matrix composite, $\pm 15^\circ$ layup angle.
- 12b Effect of steel edge strip thickness on impact stresses at the strip edge interface for 55% graphite fiber/ epoxy matrix composite $\pm 45^\circ$ layup angle.
13. Effect of Aluminum edge strip thickness on impact stresses at the strip edge interface for 55% graphite fiber/epoxy matrix composite 0° layup angle.
14. Effect of steel edge strip thickness on t_{33} stress distribution versus along edge interface for normalized thicknesses $b/a = 0.1, 1.0, 55\%$ graphite fiber/epoxy matrix composte.

*Except for Figure 6, a contact time of 35 μ sec and contact length of 2 cm was used in these calculations.

15. Effect of steel edge strip thickness on t_{11} stress distribution versus along edge interface for normalized thicknesses $b/a = 0.1, 1.0, 55\%$ graphite fiber/epoxy matrix composite.
16. Effect of steel edge strip thickness on edge interface shear stress distribution for normalized edge thickness $b/a = 0.25, 2.0, 55\%$ graphite fiber/epoxy matrix composite.

INTRODUCTION

This report is part of a continuing effort by NASA to understand the basic mechanics of foreign object impact of composite materials of particular interest are damage resistant designs of jet engine fan blades under hail or bird impact. In previous reports the central or normal impact response of composite plates was examined [1]. In this report the mechanics of edge impact of composite plates are examined. This is schematically illustrated in Figure 1.

The basic approach to the study of impact of composite plates in this program has been to examine the stress waves generated by the impact forces. For central impact of plates it has been shown that in addition to wave propagation across the plate thickness, bending and extensional waves propagate away from the impact site. The stresses associated with these waves have been studied without considering the effect of boundaries such as the free or clamped edges of a fan blade. This simplification has been made on the premise that for short impact times e.g. less than 10^{-4} sec. few edge reflections have taken place, and that the highest stresses occur at the impact site. However, for edge impact, the boundary conditions greatly affect the nature of the wave mechanics.

Edge waves in solids have been studied extensively in seismology. The principal phenomenon is the entrapment of wave energy in a layer near the surface. This surface wave is known as a Rayleigh wave and travels at a velocity below the shear velocity for isotropic solids. For plates, however, two types of edge waves can occur as shown in Figure 2a. For impact transverse to the plate, flexural edge waves can occur. For in-plane, Rayleigh type edge waves are generated. In this report only in-plane edge waves will be discussed.

Wave type solutions to the equations of elastodynamics of an orthotropic plate which exponentially decay away from the edge (X_3 direction) and propagate along the edge (X_1 direction) can be found provided the edge wave velocity satisfies the equation (Reference 9).

$$\rho v^2 + \left[\frac{C_{55} - \rho v^2}{\frac{C_{33} C_{55} (C_{11} - \rho v^2)}{C_{13} C_{33} C_{11}}} \right]^{1/2} [C_{13}^2 - C_{33} (C_{11} - \rho v^2)] = 0$$

where ρ is the massdensity of the plate and C_{ij} are the effective plate elastic constants (denoted by \hat{C}_{ij} in Reference 1). It can be shown that one real root lies in the interval

$$0 < \rho v^2 < C_{55}$$

Thus, the edge or Rayleigh wave speed is less than the shear speed in this direction $[C_{55}/\rho]^{1/2}$.

Changing the layup angle will affect the elastic constants C_{ij} and hence, change the value of the edge wave velocity. The results of this calculation are shown in Figure 2b where the C_{ij} are obtained from Reference 7. The edge wave speed seems to obtain a maximum between ± 15 and $\pm 30^\circ$ layup angle which is below the extentional wave speeds labelled "dilational" and "shear" in Figure 2b and which is greater than the bending wave velocity.

In order to prevent damage to composite fan blades under foreign object impact leading edge protection has been used. (See e.g. Ref. (8)). This usually consists of a strip of metal attached to the leading edge of the fan blade. To model the effects of this impact protection strip, the in-plane edge impact of an anisotropic plate, with a beam-strip attached to the impact edge, has been studied (see Figure 1). It will be shown later that the strip will decrease the tensile stress along the edge while producing shear stress between the strip and the plate edge.

I. BASIC EQUATIONS FOR EDGE LOADING ON ANISOTROPIC PLATE

Let the plate be the half-space $x_3 > 0$. The equations of motion are given by [1] as:

$$C_{11} u_{1,11} + C_{55} u_{1,33} + (C_{13} + C_{55}) u_{3,13} = \rho u_{1,tt} \quad (1.1)$$

$$C_{33} u_{3,33} + C_{55} u_{3,11} + (C_{13} + C_{55}) u_{1,13} = \rho u_{3,tt}$$

here we have employed $C_{11}, C_{13}, C_{33} \dots$ to denote $\hat{C}_{11}, \hat{C}_{13}, \hat{C}_{33} \dots$ of [1]. The in-plane motion is assumed to be independent of the bending deformation. With the loading condition shown in Figure 1, the boundary conditions are (without protection strip):

$$t_{13}(x_1, 0, t) = C_{55}(u_{1,2} + u_{3,1}) \Big|_{x_3=0} = 0 \quad (1.2)$$

$$t_{33}(x_1, 0, t) = [C_{33} u_{3,3} + C_{13} u_{1,1}] \Big|_{x_3=0} = p f(x_1) g(t)$$

The following nondimensional parameters are used;

$$C_{11}^* = C_{11}/C_{66}, \quad C_{13}^* = C_{13}/C_{66}, \quad C_{33}^* = C_{33}/C_{66}, \quad C_{55}^* = C_{55}/C_{66}, \quad P_0^* = p/C_{66} \quad (1.3)$$

$$u_1^* = u_1/\ell, \quad u_3^* = u_3/\ell, \quad x_1^* = x_1/\ell, \quad x_3^* = x_3/\ell, \quad t^* = t \sqrt{C_{66}/\rho}/\ell \quad (1.4)$$

ℓ is a length parameter. C_{66} is a typical elastic constant. In what follows the equations will be assumed to be nondimensionalized using (1.3) and (1.4).

To obtain the solution, we employ transform methods. Define:

$$F(f) = \frac{1}{2\pi} \int_{-\infty}^{\infty} e^{-ik_1 x_1} f(x_1) dx_1$$

as the Fourier transform of $f(x)$ where we assume that

$$f(x_1) \Big|_{-\infty}^{\infty} = \frac{\partial}{\partial x_1} f(x_1) \Big|_{-\infty}^{\infty} = 0$$

Then

$$F\left(\frac{\partial}{\partial x_1} f\right) = ik F(f), \quad F\left(\frac{\partial^2}{\partial x_1^2} f\right) = -k_1^2 F(f)$$

Also define

$$\mathcal{L}(f) = \int_0^{\infty} e^{-st} f(t) dt$$

as the Laplace transform. The initial conditions are assumed to be,

$$u_1(x_1, x_3, 0) = \frac{\partial}{\partial t} u_1(x_1, x_3, 0) = 0 \quad (1.5)$$

$$u_3(x_1, x_3, 0) = \frac{\partial}{\partial t} u_3(x_1, x_3, 0) = 0$$

Letting $\tilde{u}_1 = \tilde{u}_1(k, x_3, s)$, $\tilde{u}_3 = \tilde{u}_3(k, x_3, s)$, we have the following transformed equation:

$$C_{11}(-k^2) \tilde{u}_1 + C_{55} \tilde{u}_{1,33} + (C_{13} + C_{55}) (ik_1) \tilde{u}_{3,3} = +s^2 \tilde{u}_1 \quad (1.6)$$

$$C_{33} \tilde{u}_{3,33} + C_{55}(-k^2) \tilde{u}_3 + (C_{13} + C_{55}) (ik_1) \tilde{u}_{1,3} = +s^2 \tilde{u}_3$$

and at $x_3 = 0$, the transformed boundary conditions become

$$\tilde{u}_{1,3} + ik_1 \tilde{u}_3 = 0 \quad (1.7)$$

$$C_{33} \tilde{u}_{3,3} + C_{13} ik_1 \tilde{u}_1 = -p_0 \overline{f(k_1)g(s)}$$

Since we are expecting surface wave propagation, we seek the solution of (1.6), (1.7) in the forms:

$$\begin{bmatrix} \tilde{u}_1 \\ \tilde{u}_3 \end{bmatrix} = \begin{bmatrix} \phi_1 \\ \phi_2 \end{bmatrix} e^{-p(k,s)x_3} \quad (\text{real } (p) \geq 0) \quad (1.8)$$

Therefore, the equations for ϕ_1 , ϕ_2 are:

$$\begin{bmatrix} -s^2 - C_{11} k_1^2 + p^2 C_{55} & -ik_1 p(C_{13} + C_{55}) \\ -ik_1 p(C_{13} + C_{55}) & -s^2 - k_1^2 C_{55} + p^2 C_{33} \end{bmatrix} \begin{bmatrix} \phi_1 \\ \phi_2 \end{bmatrix} = 0 \quad (1.9)$$

or for a non-trivial solution,

$$\begin{aligned} \det = C_{33} C_{55} p^4 + [C_{33}(-s^2 - C_{11} k_1^2) + C_{55}(-s^2 - C_{55} k_1^2) + k_1^2 (C_{13} + C_{55})^2] p^2 \\ + (s^2 + C_{11} k_1^2)(s^2 + C_{55} k_1^2) = 0 \end{aligned} \quad (1.10)$$

We will choose the p's with positive real parts to ensure the decay in x_3 direction of the surface wave. Let the solutions be $p = p_1, p_2$, therefore, we have

$$p \neq p_1 : \phi_1^{(1)} \equiv C_1(k_1, s), \quad \phi_2^{(1)} = -\frac{i[-s^2 - C_{11} k_1^2 + C_{55} p_1^2]}{k_1 p_1 (C_{13} + C_{55})} \quad (1.11)$$

$$p = p_2 : \phi_1^{(2)} \equiv C_2(k_1, s), \quad \phi_2^{(2)} = \psi_{32} C_2 \equiv -\frac{i[-s^2 - C_{11} k_1^2 + C_{55} p_2^2]}{k_1 p_2 (C_{13} + C_{55})} \quad (1.11)$$

Therefore, the displacements have the forms:

$$\begin{bmatrix} \bar{u}_1 \\ \bar{u}_3 \end{bmatrix} = C_1(k_1, s) \begin{bmatrix} 1 \\ \psi_{31} \end{bmatrix} e^{-p_1 x_3} + C_2(k_1, s) \begin{bmatrix} 1 \\ \psi_{32} \end{bmatrix} e^{-p_2 x_3} \quad (1.12)$$

C_1 , C_2 are determined from the boundary conditions (1.7), or

$$\begin{bmatrix} -p_1 + ik_1 \psi_{31} & -p_2 + ik_1 \psi_{32} \\ -p_1 C_{33} \psi_{31} + ik_1 C_{13} & -p_2 C_{33} \psi_{32} + ik_1 C_{13} \end{bmatrix} \begin{bmatrix} C_1 \\ C_2 \end{bmatrix} = \begin{bmatrix} 0 \\ -p_0 \bar{fg} \end{bmatrix} \quad (1.13)$$

Here, the determinant, $\Delta(p_1, s)$, given by,

$$\begin{aligned} \Delta = & (ik_1 \psi_{31} - p_1) (ik_1 C_{13} - p_2 C_{33} \psi_{32}) \\ & - (ik_1 \psi_{32} - p_2) (ik_1 C_{13} - p_1 C_{33} \psi_{31}) \end{aligned} \quad (1.14)$$

must be non-zero to ensure a solution. ($\Delta=0$ gives the Rayleigh poles of the system, which correspond to a free surface). Therefore,

$$C_1 = \frac{1}{\Delta} [ik_1 \psi_{32} - p_2] \bar{fg} p_0 \quad (1.15)$$

$$C_2 = \frac{1}{\Delta} [p_1 - ik_1 \psi_{31}] \bar{fg} p_0$$

and the physical displacements $u_1(x_1, x_3, t)$, $u_3(x_1, x_3, t)$ are obtained by inverting their transforms.

From the stress-strain relations

$$\begin{aligned} t_{13} &= C_{55}(u_{1,3} + u_{3,1}), \quad t_{11} = C_{11}u_{1,1} + C_{13}u_{3,3}, \\ t_{33} &= C_{33}u_{3,3} + C_{13}u_{1,1} \end{aligned} \quad (1.16)$$

we obtain the transforms of the stresses

$$\begin{aligned} \bar{t}_{13} &= C_{55}\{(-p_1 + ik_1 \psi_{31}) C_1 e^{-p_1 x_3} \\ &\quad + (-p_2 + ik_1 \psi_{32}) C_2 e^{-p_2 x_3}\} \\ \bar{t}_{11} &= (C_{11}ik_1 - C_{13}p_1 \psi_{31}) C_1 e^{-p_1 x_3} \end{aligned} \quad (1.17)$$

$$\begin{aligned} \bar{t}_{33} &= (-p_1 \psi_{31} C_{33} + ik_1 C_{13}) C_1 e^{-p_1 x_3} \\ &\quad + (-p_2 \psi_{32} C_{33} + C_{13}ik_1) C_2 e^{-p_2 x_3} , \end{aligned}$$

and the physical stresses can be obtained by inversion.

The particular forcing function employed is

$$f(x_1) g(t) = [1 - \left(\frac{x_1}{a}\right)^2] \sin \frac{\pi t}{\tau_0} \quad 0 < t < \tau_0 \quad |x_1| \leq a$$

(1.18)

$$= [1 - \left(\frac{\lambda}{a}\right)^2 x_1^{*2}] \sin (\pi t^*/\tau_0^*)$$

where $\tau_0^* \equiv \lambda / \sqrt{C_{66}/\rho}$.

Here a is a length measuring the impact area, and τ_0 is the contact time [1]. The transform of this particular forcing function, in non-dimensional form becomes,

$$\overline{fg} = + \frac{4}{k^2(a/\lambda)^2} \left[-\frac{a}{\lambda} \cos k_1 \left(\frac{a}{\lambda}\right) + \sin k_1 \left(\frac{a}{\lambda}\right) \right] \frac{\pi \tau_0^* (1 + e^{-s\tau_0^*})}{\pi^2 + \tau_0^{*2} s^2} .$$

(1.19)

II. EDGE IMPACT OF PLATE WITH EDGE PROTECTION

To prevent failure of composite fan blades under impact forces, leading edge protective strips have been employed. In practice, these strips of stainless steel are wrapped around the leading edge. To model this device, we consider a beam bonded to the edge of an anisotropic plate (Figure 1). The effect of the beam will be to thwart the force of impact, thereby decreasing the normal stresses in the composite. However, we shall show that with such a reduction in normal stress, sizeable interface shear stresses can be induced.

With the introduction of a beam of thickness b on the edge of the composite plate, the Rayleigh wave behavior will depend on the ratio of the wavelength to thickness ratio of each Fourier component in the x_1 direction. Thus one should expect the Rayleigh wave speed to vary with b/a , the thickness to impact footprint ratio. In addition the Rayleigh wave will become distorted as it propagates.

To solve the edge strip problem the solution in the composite plate follows the same procedure as the no-strip case except for the boundary conditions on the edge. In place of the zero stress conditions on the edge we relate the edge stresses t_{33} , t_{13} to the motion of the beam strip. If one considers a small element of the beam-strip along the x_1 direction, the momentum balance equations in the x_1 , x_3 directions become, (for a plate of unit thickness)

$$\rho b \frac{\partial^2 U}{\partial t^2} = E b \frac{\partial^2 U}{\partial x_1^2} + t_{13} \quad (2.1)$$

$$\frac{\rho b}{\partial t^2} \frac{\partial^2 W}{\partial x_1^4} = - EI \frac{\partial^4 W}{\partial x_1^4} + I_p b \frac{\partial^4 W}{\partial x_1^2 \partial t^2} + \frac{b}{2} \frac{\partial t_{13}}{\partial x_1} + t_{33} + p_0^{fg} \quad (2.2)$$

In these equations U, W are the x_1, x_3 displacements of the beam element at the half thickness, and t_{33}, t_{13} are the interface stresses.

We choose the compatibility conditions between the beam and plate displacements

$$W = u_3, \text{ on } x_3 = 0. \quad (2.3)$$

$$U = u_1 + \frac{b}{2} \frac{\partial u_3}{\partial x_1}, \text{ on } x_3 = 0 \quad (2.4)$$

In the above equations b is the depth of the strip, E, I, I_p are respectively the Young's modulus, moment of inertia and rotary inertia. Also $p f(t) g(x_1)$ is the edge loading now applied to the outer protective strip surface.

The equations for the plate remain as in the free edge case and a solution is obtained by taking a Laplace transform on time and a Fourier transform on the space variable x_1 . With nondimensionalization the solution in the plate is assumed in the form of (1.12). The transform of the plate displacements are

$$\begin{bmatrix} \bar{u}_1 \\ \bar{u}_3 \end{bmatrix} = C_1 \begin{bmatrix} 1 \\ \psi_{31} \end{bmatrix} e^{-p_1 x_3} + C_2 \begin{bmatrix} 1 \\ \psi_{32} \end{bmatrix} e^{-p_2 x_3} \quad (2.5)$$

where p_1, p_2 are defined in (1.10) and ψ_{31}, ψ_{32} are given in (1.11). C_1, C_2 are determined from the edge boundary conditions. However, in place of the free edge conditions (1.2) we use the equations of motion for the strip (2.1),

(2.2). C_1, C_2 are then solutions to the algebraic equations

$$\begin{bmatrix} G_1 & H_1 \\ G & H \end{bmatrix} \begin{bmatrix} C_1 \\ C_2 \end{bmatrix} = \begin{bmatrix} 0 \\ -p_o^* \bar{fg} \end{bmatrix} \quad (2.6)$$

where

$$G_1 = -k^2 Ew + p_1 C_{55} - \rho ws^2 - \psi_{31} (ik^2 w^2 E/2 + ikC_{55} + \rho w^2 s^2 ik/2)$$

$$H_1 = -k^2 Ew + p_2 C_{55} - \rho ws^2 - \psi_{32} (ik^3 w^2 E/2 + ikC_{55} + \rho w^2 s^2 ik/2)$$

$$\begin{aligned} G = & -ikC_{13} + ikwp_1 C_{55}/2 + \psi_{31} (p_1 C_{33} + Ew^2 k^4/12 + wk^2 C_{55}/2 \\ & + k^2 s^2 \rho w^3/2 + \rho ws^2) \end{aligned}$$

$$\begin{aligned} H = & -ikC_{13} + ikwp_2 C_{55}/2 + \psi_{32} (p_2 C_{33} + Ew^2 k^4/12 + wk^2 C_{55}/2 \\ & + k^2 s^2 \rho w^3/2 + \rho ws^2) \end{aligned} \quad (2.7)$$

where $w = b/\ell$, ρ , E , are nondimensionalized quantities and $p_1, p_2, \psi_{31}, \psi_{32}$ are defined in (1.11).

III. NUMERICAL INVERSION

The inversions are accomplished by the Fast Fourier Transform (FFT) techniques [2], which consists of a transformation from Laplace to Fourier transforms, and a two-dimensional numerical inversion using the usual FFT algorithm. Notice the Laplace inversion formula

$$f(t) = \frac{1}{2\pi i} \int_{\Gamma}^{C+i\infty} f(s) e^{st} ds$$

Set $s = C + i\alpha$

$$f(t) = \frac{1}{2\pi} \int_{-\infty}^{\infty} f(C+i\alpha) e^{Ct} e^{i\alpha t} d\alpha \quad (3.1)$$

where C and α are both real, and C is greater than the largest real part of all singularities of $f(s)$. Numerically, the double Fourier transform (or inversion) has the following form [1]:

$$f(x, t) \approx \frac{K_x K_t}{\pi^2 NM} e^{-i[K_x(1-\frac{1}{N})x + K_t(1-\frac{1}{M})t]} \sum_{I=1}^N \sum_{J=1}^M \bar{f}(I, J) e^{2\pi i [\frac{(I-1)x}{N} + \frac{(J-1)}{M} t]} \quad (3.2)$$

where N, M are the number of points in x and t direction respectively, and K_x, K_t are the corresponding half-frequency range.

For the present problem, the determination of C is through the following considerations:

The form of inversion integrals are, in general,

$$I = \frac{1}{2\pi i} \int_{C-i\infty}^{C+i\infty} \frac{F(k_1, s)}{\Delta(k_1, s)} e^{-px_3} e^{st} ds \quad p = p(k_1, s), \operatorname{Re}(p) \geq 0 \quad (3.3)$$

and Δ is given by (1.14). It is easy to see the singularities of the integral of (2.3) are:

a) Poles at $\Delta = 0$,

$$\Delta = (p_2 - p_1) ik_1 (C_{13} - \psi_{31} \psi_{32} C_{33}) + (\psi_{32} - \psi_{31}) (k_1^2 C_{13} + p_1 p_2 C_{33}) = 0 \quad (3.4)$$

implies

$$(p_2 - p_1) [C_{13} k_1^2 p_1 p_2 (C_{13} + C_{55})^2 + C_{33} (C_{55} p_1^2 - s^2 - C_{11} k_1^2) (C_{55} p_2^2 - s^2 - C_{11} k_1^2)] - (C_{13} + C_{55}) [p_1 (C_{55} p_2^2 - s^2 - C_{11} k_1^2) - p_2 (C_{55} p_1^2 - s^2 - C_{11} k_1^2)] (k_1^2 C_{13} + p_1 p_2 C_{33}) = 0 \quad (3.5)$$

Interpretation of this condition is best understood
for the particular case of an isotropic material, i.e. for

$$C_{11} = \lambda + 2\mu = C_{33}, \quad C_{13} = \lambda, \quad C_{55} = \mu,$$

$$\text{choose } C_{66} = C_{55} = \mu$$

It is easy to see that from (1.10), (1.11)

$$\det = [\mu p_1^2 - (\mu k_1^2 + \rho s^2)] \{(2\mu + \lambda) p_1^2 - [(\lambda + 2\mu) k_1^2 + \rho s^2]\}$$

$$p_1^2 = (\mu k_1^2 + \rho s^2)/\mu, \quad p_2^2 = [(\lambda + 2\mu) k_1^2 + \rho s^2]/(\lambda + 2\mu)$$

$$\psi_{31} = ik_1/p_1, \quad \psi_{32} = -p_2/ik_1,$$

Here $[\mu/\rho]^{1/2} \equiv v_s$, is the shear wave speed and $[(\lambda + 2\mu)/\rho]^{1/2} v_p$, is the longitudinal or pressure wave speed for isotropic materials.

Thus for the isotropic case that, $\Delta = 0$ implies

$$4\mu p_2 + \left(p_1 + \frac{k^2}{p_1}\right) \left[\lambda + \frac{p_2^2}{k^2} (\lambda + 2\mu)\right] = 0 \quad (3.6)$$

where p_1, p_2 are defined above. This is the equation for the Rayleigh wave speed $v_R \equiv (is/k)^{1/2}$ which is found as a real root of (3.6) (see e.g. [3]).

For the case $\lambda = \mu$ (Poissons ratio = 0.25), $v_R = 0.919 v_s$.

For the anisotropic case a computational scheme to calculate the zeroes of (3.5) has been written, (Figure 2).

b) Branch points: The branch points of the integrand in (3.3) are the same as those of the functions $p_1(k, s)$, $p_2(k, s)$, they are:

i) $p_1 = 0$, or $p_2 = 0$ which implies $(C_{11} k^2 + \rho s^2)(C_{55} k^2 + \rho s^2) = 0$
i.e., $k/s = \pm i\sqrt{\rho/C_{55}}$, $\pm i\sqrt{\rho/C_{11}}$ pure imaginary.

These correspond to longitudinal and shear wave speeds for an isotropic material

ii) $p_{1,2} = \pm \sqrt{-B \pm \sqrt{B^2 - 4AC}} / 2A \quad (3.7)$

with $A = C_{33} C_{55} > 0$

$$B = -\rho s^2 (C_{33} + C_{55}) + k^2 [(C_{13} + C_{55})^2 - C_{11} C_{33} - C_{55}^2]$$

$$C = (C_{11} k^2 + \rho s^2) (C_{55} k^2 + \rho s^2)$$

These branch points are those values of s/k which render $B - 4AC = 0$, and are branch points of second order.^[4] The distribution of these points is shown in Figure 3. It has been shown [5] that the contribution of these branch points to the value of the integrals (3.3) is important only when one considers the multi-reflected and refracted waves in layered media, or when the position of interest is very close to the impact origin. In this study we were more concerned with how the energy is propagated away from the impact point, which is mainly associated with surface waves, thus we ignored the contribution of these branch points.^[5]

The contour of integration for the Laplace inversion is as shown in Figure 3. Notice the branch cuts are extended to negative infinity, in accordance with the requirement that $C > \max$ real part of the singularities. The requirement that $\text{real}(p) \geq 0$ also determines the correct sheet of the Riemann surfaces. Numerically, since the branch points are located at $s/k = \text{constant}$, as k gets large C should be large, and the factor e^{ct} in the Laplace inversion expression will rise sharply to an unmanageable size. Since, in the last paragraph, we have noticed the contribution of the branch points is unimportant, a path Γ_2 is chosen to replace Γ_1 by the Cauchy's integral theorem. Notice the advantage of integration along Γ_2 is that C_0 is a positive constant independent of k . The determination of optimal C_0 is discussed in [2]. Here, in order to minimize the aliasing and round off errors in numerical computations simultaneously, we choose

$$C_0 = \frac{2}{3M\lambda_t} \ln (\hat{g}/\hat{r}) \quad (3.9)$$

where $\hat{g} = p_0/C_{66}$, $\hat{r} = 10^{-6} \times \frac{1}{\lambda_t}$. λ_t is a small time interval, less than the impact contact time. Further details are given in Appendix A.

IV. RESULTS

A computer program has been written to calculate the stresses in a plate with an elastic beam on one edge under a transient impact load distribution along the edge. A program description, flow charts, input data formats, and sample printout of the program are contained in the appendices to this report. In this section we will summarize some of the results obtained from this computer program. These results were calculated for an anisotropic plate with effective elastic constants of 55% graphite fiber/epoxy matrix composite obtained from Reference 7 and summarized in the Table.

No-strip case:

The Rayleigh wave can be seen in the stress t_{11} on the edge as shown in Figures 4, 5 for a graphite fiber-epoxy composite for layup angles $0, \pm 15^\circ$. After the initial contact time, the stress is observed to propagate with little change at a speed near the calculated Rayleigh speed (Figure 2). This wave can be observed in the computed output in the space-time ($x_1, -t$) plane Figure 7, as a band of non-zero values along a diagonal from the upper left to the lower right corner of the $x_1, -t$ plane. Caution is urged in using this program since spurious waves can enter the calculations due to the periodic nature of the finite numerical Fourier Transform. These spurious waves are data bands which lie along diagonals from upper right to lower left. In other words, only disturbances emanating from the impact source in the upper left corner of the $x_1 - t$ plane of Figure 7 should be valid. A computer map of the space time history of the edge impact stress is shown in Figure 6. A contact time of 35 μ sec and contact length 2 cm was used in these calculations.

As is characteristic of surface wave effects, the stresses due to impulsive loading on the edge decrease with distance from the edge. This is shown in Figure 8 for two different layup angles. The normal stress t_{33} appears to decrease to about 1/4 of its value on the surface at a depth equal to one half of the loading length a . The rate of decay from the edge depends on the layup angle. Another characteristic of edge impact is the development of tension in the normal stress t_{33} under the impact point. This is shown in Figure 9. Thus while the compression part decreases with distance from the edge a tension tail develops in the wave.

The effect of layup angle on the impact stresses can be seen in Figures 10, 11. The stress t_{11} at the edge is larger than the impact pressure and decreases as the layup angle goes from 0° to $\pm 45^\circ$ (Figure 10).

Below the surface or edge, the peak normal stress t_{33} at $x_1 = 0$ is a minimum for layup angles near $\pm 30^\circ$, while the shear stress t_{13} increases as the fiber angle goes from 0° to $\pm 45^\circ$ (Figure 10).

An unexpected result is the shift of the maximum normal stress t_{33} to points off the impact axis $x_1 = 0$ for layup angles greater than about ± 30 . A pronounced peak in t_{33} versus x_1 , beyond the impact pressure foot print, can be seen in Figure 11 for $\pm 45^\circ$ layup angle.

Impact protection strip case:

The effect of bonding an edge impact protection strip to the half plane is shown in Figures 12-16. In Figures 12, 13, the increase in the thickness of a steel strip produces a decrease in the interface stresses

t_{11} , t_{33} but creates an interface shear stress at the strip-composite interface. This shear stress reaches a maximum for strip thickness less than the impact footprint length and decreases for greater strip thicknesses. Thus, if the strip is too thin, debonding can occur under impact due to induced interface shear.

In Figure 14 one can see that increasing the strip thickness decreases the peak normal stress t_{33} and redistributes the load over a longer length under the strip. However, while the peak compression stress is decreased by the strip, tension is created which could also produce debonding of the strip from the composite.

For the no-strip case a Rayleigh wave was seen to propagate along the edge relatively unperturbed (Figures 4, 5). With the strip present, (Fig.15) this wave becomes distorted as time increases. In fact, the beam-strip boundary conditions introduce dispersion in the edge waves which make the Rayleigh edge wave velocity dependent in the effective wave length of the disturbance.

Finally in Figure 16 shear stress distributions along the strip-composite interface are shown for a thickness near the shear peak ($b/a = 0.25$) and another for $b/a = 2.0$. In the latter case the shear is distributed over a larger length resulting in a lower peak stress. Also the strip delays the time of maximum shear from $1/2$ to $3/4 T_0$

Summary of Results

An analytical-numerical method has been developed to solve the response of a composite plate with a bonded edge strip to in-plane impact type forces on the edge. Results of computer simulations reveal the following:

- 1) Rayleigh edge waves can propagate away from the impact site with tension and compression up to values of the impact pressure, depending on layup angle.
- 2) Normal to the edge, the initial peak compression pulse decreases as it propagates into the plate but a tension tail develops as it propagates away from the impact site.
- 3) The edge stress t_{11} under impact is decreased as the fiber layup angle goes from 0° to $\pm 45^\circ$.
- 4) Protection strips of thickness less than half the impact length can develop large interface shear under impact.
- 5) The normal and edge stresses t_{33} , t_{11} at the edge can be decreased significantly by protection strips of thickness greater than the half impact length.

APPENDIX A

The Determination of Parameter C_0

Consider the Laplace inversion of a function $g(t)$ as

$$g(t) = \frac{1}{2\pi i} \int_{C_0 - i\infty}^{C_0 + i\infty} \bar{g}(s) e^{st} ds \quad (A.1)$$

and let $s = C_0 + i\omega$, C_0 and ω are real. We can change (A.1) into the Fourier inversion formula

$$g(t) = \frac{1}{2\pi} e^{C_0 t} \int_{-\infty}^{\infty} \bar{g}(C_0 + i\omega) e^{i\omega t} d\omega \equiv e^{C_0 t} x(t) \quad (A.2)$$

which is then inverted by the Fast Fourier Transform technique. In the FFT scheme, a continuous function $\bar{g}(C_0 + i\omega)$ is discretized and the infinite interval of integration is truncated. The error due to truncation depends on each problem but doesn't depend on C_0 , thus in the determination of C_0 , we will assume the truncation error is negligible. It is shown [2] that the discretizing of the transform in one domain will cause aliasing error in the other domain, e.g. sampling \bar{g} at N points in a frequency interval, $0 < \omega < \Omega$, will produce a transformed function $x_p(t)$ which is periodic and which differs substantially from $x(t)$ for large enough t . For even $x(t)$ this difference can be shown [2] to be given by,

$$x_p(t) \approx x(t) + x(t-T)$$

for $0 < t < T/2$ where $T = N/\Omega$.

It has been shown [2] also that the aliasing error is approximated by $E_a(t) = e^{-C_o(T-2t)} g(T-t)$ for the Laplace inversion (A.2).

Notice the aliasing error is a decreasing function of C_o .

The other source of error is of course the round off error in computation. Since we multiply the resulting $x(t)$ by $e^{C_o t}$ to get $g(t)$, the rounding error is of the form

$$Er(t) = e^{C_o T} r(t).$$

The error bounds are then

$$\left. \begin{aligned} \varepsilon_1 &= |\text{Max } Ea(t)| = e^{-C_o(T-2\tau)} \text{Max}|g(T-t)| \\ \varepsilon_2 &= |\text{Max } Er(t)| = e^{C_o \tau} \text{Max}|r(t)| \end{aligned} \right\} \quad 0 \leq t \leq \tau$$

Equating ε_1 and ε_2 , the optimal C_o is then

$$C_o = \frac{\ln(\text{Max } g(T-t)/\text{Max } r(t))}{T-\tau}$$

Chosing $\tau = T/4$, therefore

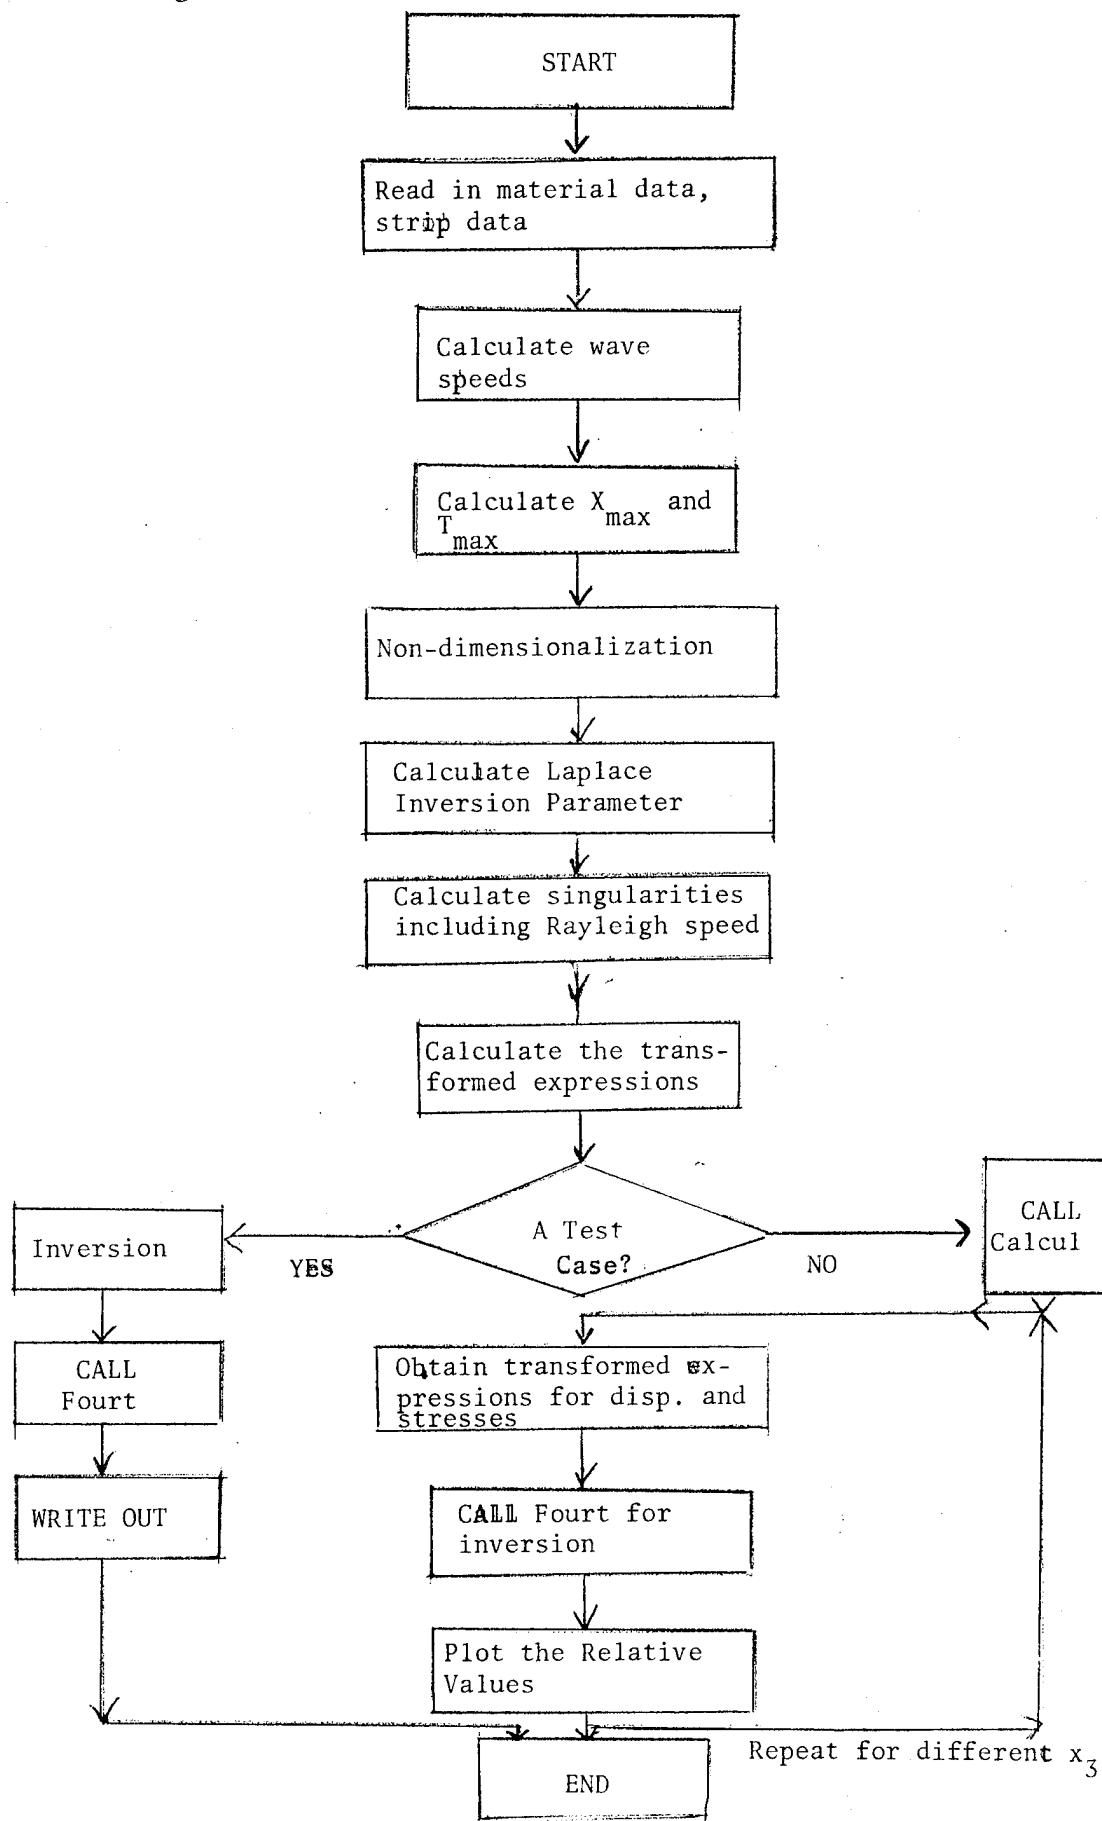

$$C_o = \frac{4}{3T} \ln(\hat{g}/\hat{r}), \quad \hat{g} \equiv \text{Max } g(T-t), \quad \hat{r} \equiv \text{Max } r(t)$$

Notice, empirically, $\hat{r} \approx 2 \frac{N}{T} 10^{-6}$ on single precision IBM 360 systems.

APPENDIX C

NOTES ON COMPUTER PROGRAM

The choice of scales is very essential to the success of the present computational method. It is noticed that the accuracy depends on the number of points employed and the range of frequency spectra covered. Considering limitations of both computer storage and time, a time-space grid of 32×64 points was chosen for $t > 0$, $x_1 > 0$. Thus, the non-dimensionalization of all equations and quantities are both necessary and important to the obtaining of meaningful data from the limited grid size.

The numerical inaccuracies introduced have several origins:

1. Theoretically, error has been introduced by the neglecting of the outer branch points contributions. It has been shown, for isotropic cases, the contributions of these branch points behaved like r^{-2} at large distance from a delta function loading at the origin $r = 0$. Compared with the $r^{\frac{1}{2}}$ decreases of the contribution of the residue. Thus, for small r , or near the origin, the errors might be significant. An asymptotic form of the behavior of small r has been deduced for a simple delta loading at origin on an isotropic half-space []. It is shown the error thus introduced is of the order of 5% maximum response in stress.
2. The aliasing error introduced through the periodizing of the functions.
3. The round-off error in Laplace inversion along with aliasing error. have been discussed in the determination of C_o (Appendix A). It is

found that error 3 is more serious of the two. Hence in calculations the maximum non-dimensionalized time should be restricted to below 6 or 8 for reasonably good results.

4. Errors due to reflections at the boundary. Since the space grid is finite, it has been observed that whenever a wave hit the boundary of chosen space, a sizable numerical error will start propagating in, as if the wave were reflected from the boundary. The basic reason is due to the periodization of the space (x_1) domain. In computation, this error should be avoided. To correctly determine the extent of the space (x_1) domain, a priori recognition of significant wave speed (at which most of the energy travels) is important. Usually an estimation will be sufficient. Then the proper nondimensionalizing constants can be chosen.

JOB 0350 7/5/74 IBM 360-91

EXECUTION TIME 34 SEC.

25 PAGES

CORE 150 K

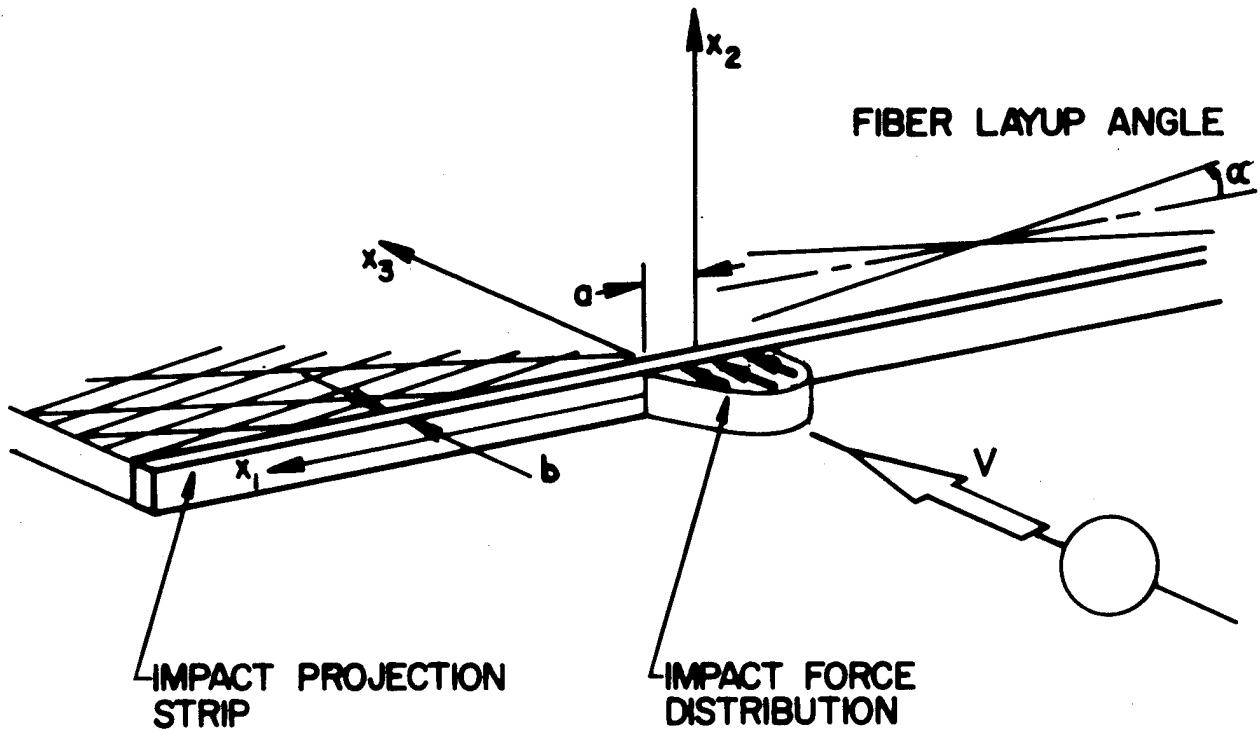

FIGURE 1

GEOMETRY OF IN-PLANE EDGE IMPACT OF
A COMPOSITE PLATE WITH PROJECTION STRIP

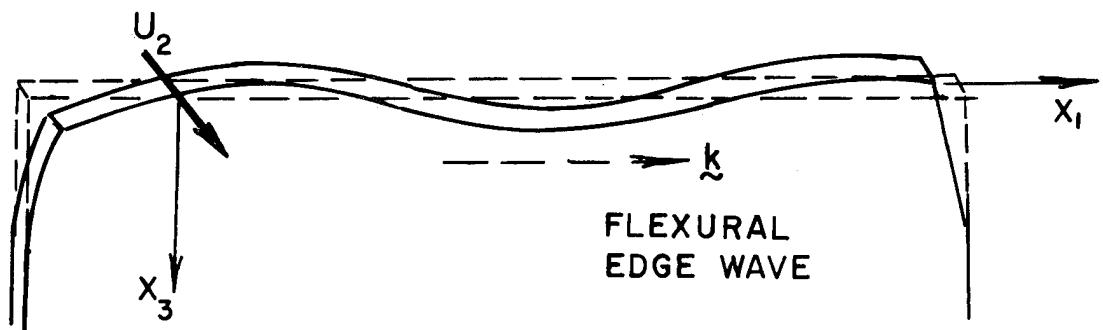

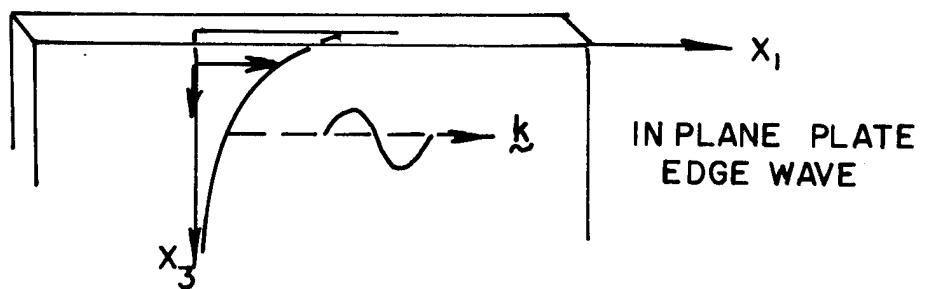

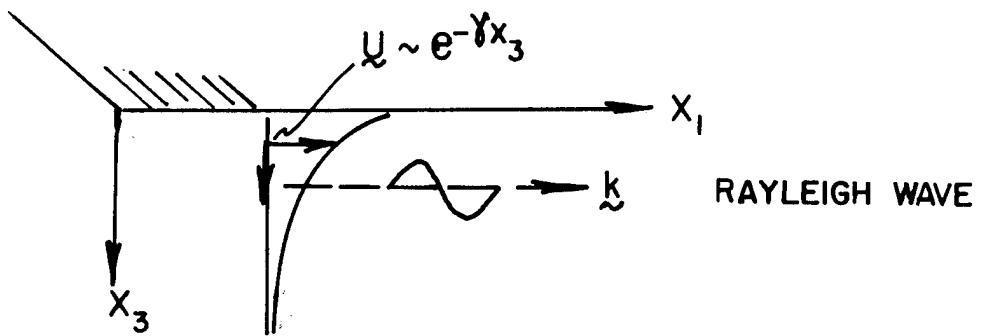

FIGURE 2a

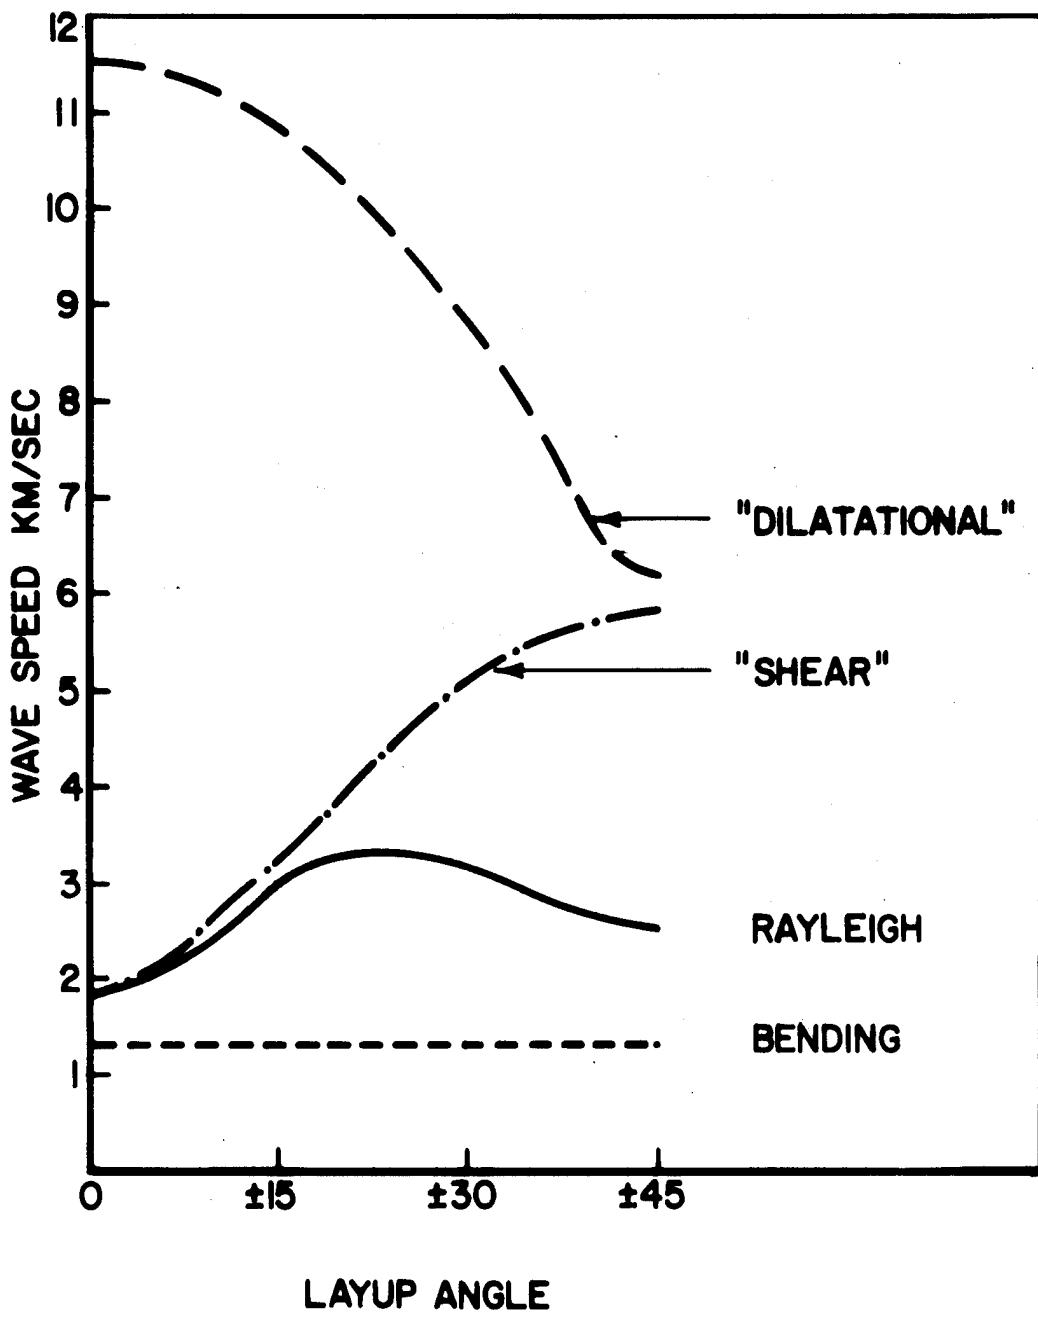

FIGURE 2b

Comparison of In-plane plate edge wave speed with body wave speeds versus fiber layup angle for 55% graphite fiber/epoxy matrix composite.

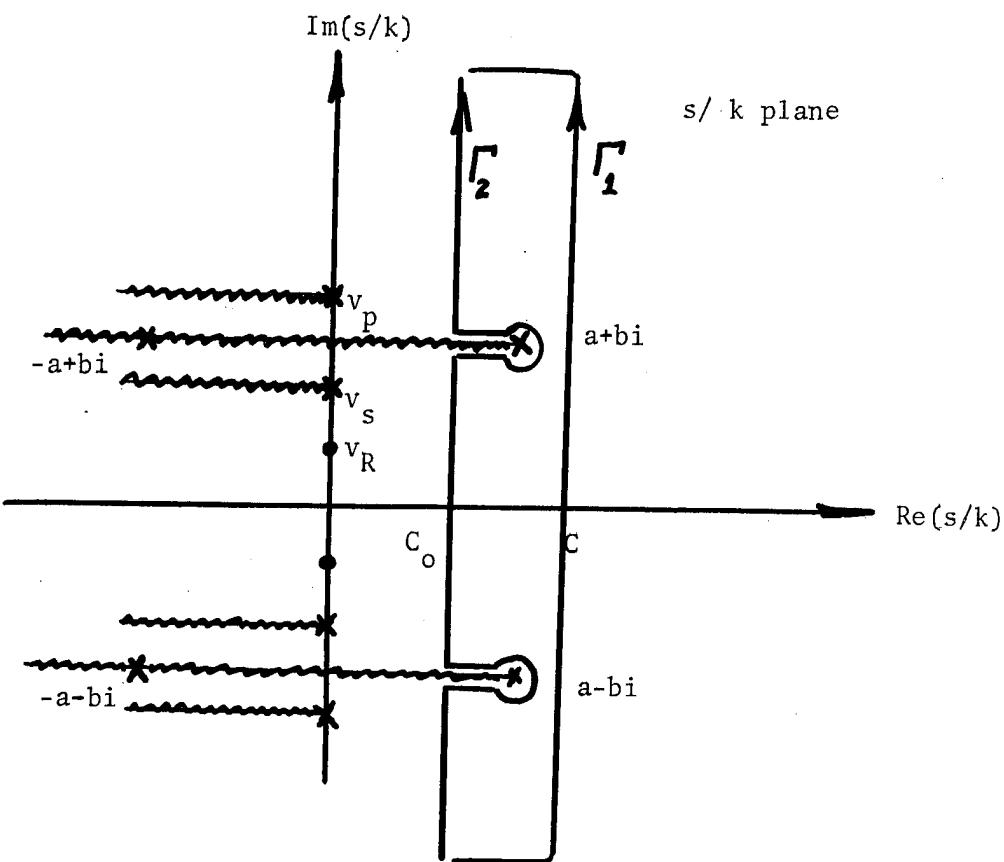

FIGURE 3.

Poles, Branch Points and Integration Contours in the complex Plane for the Numerical Solution.

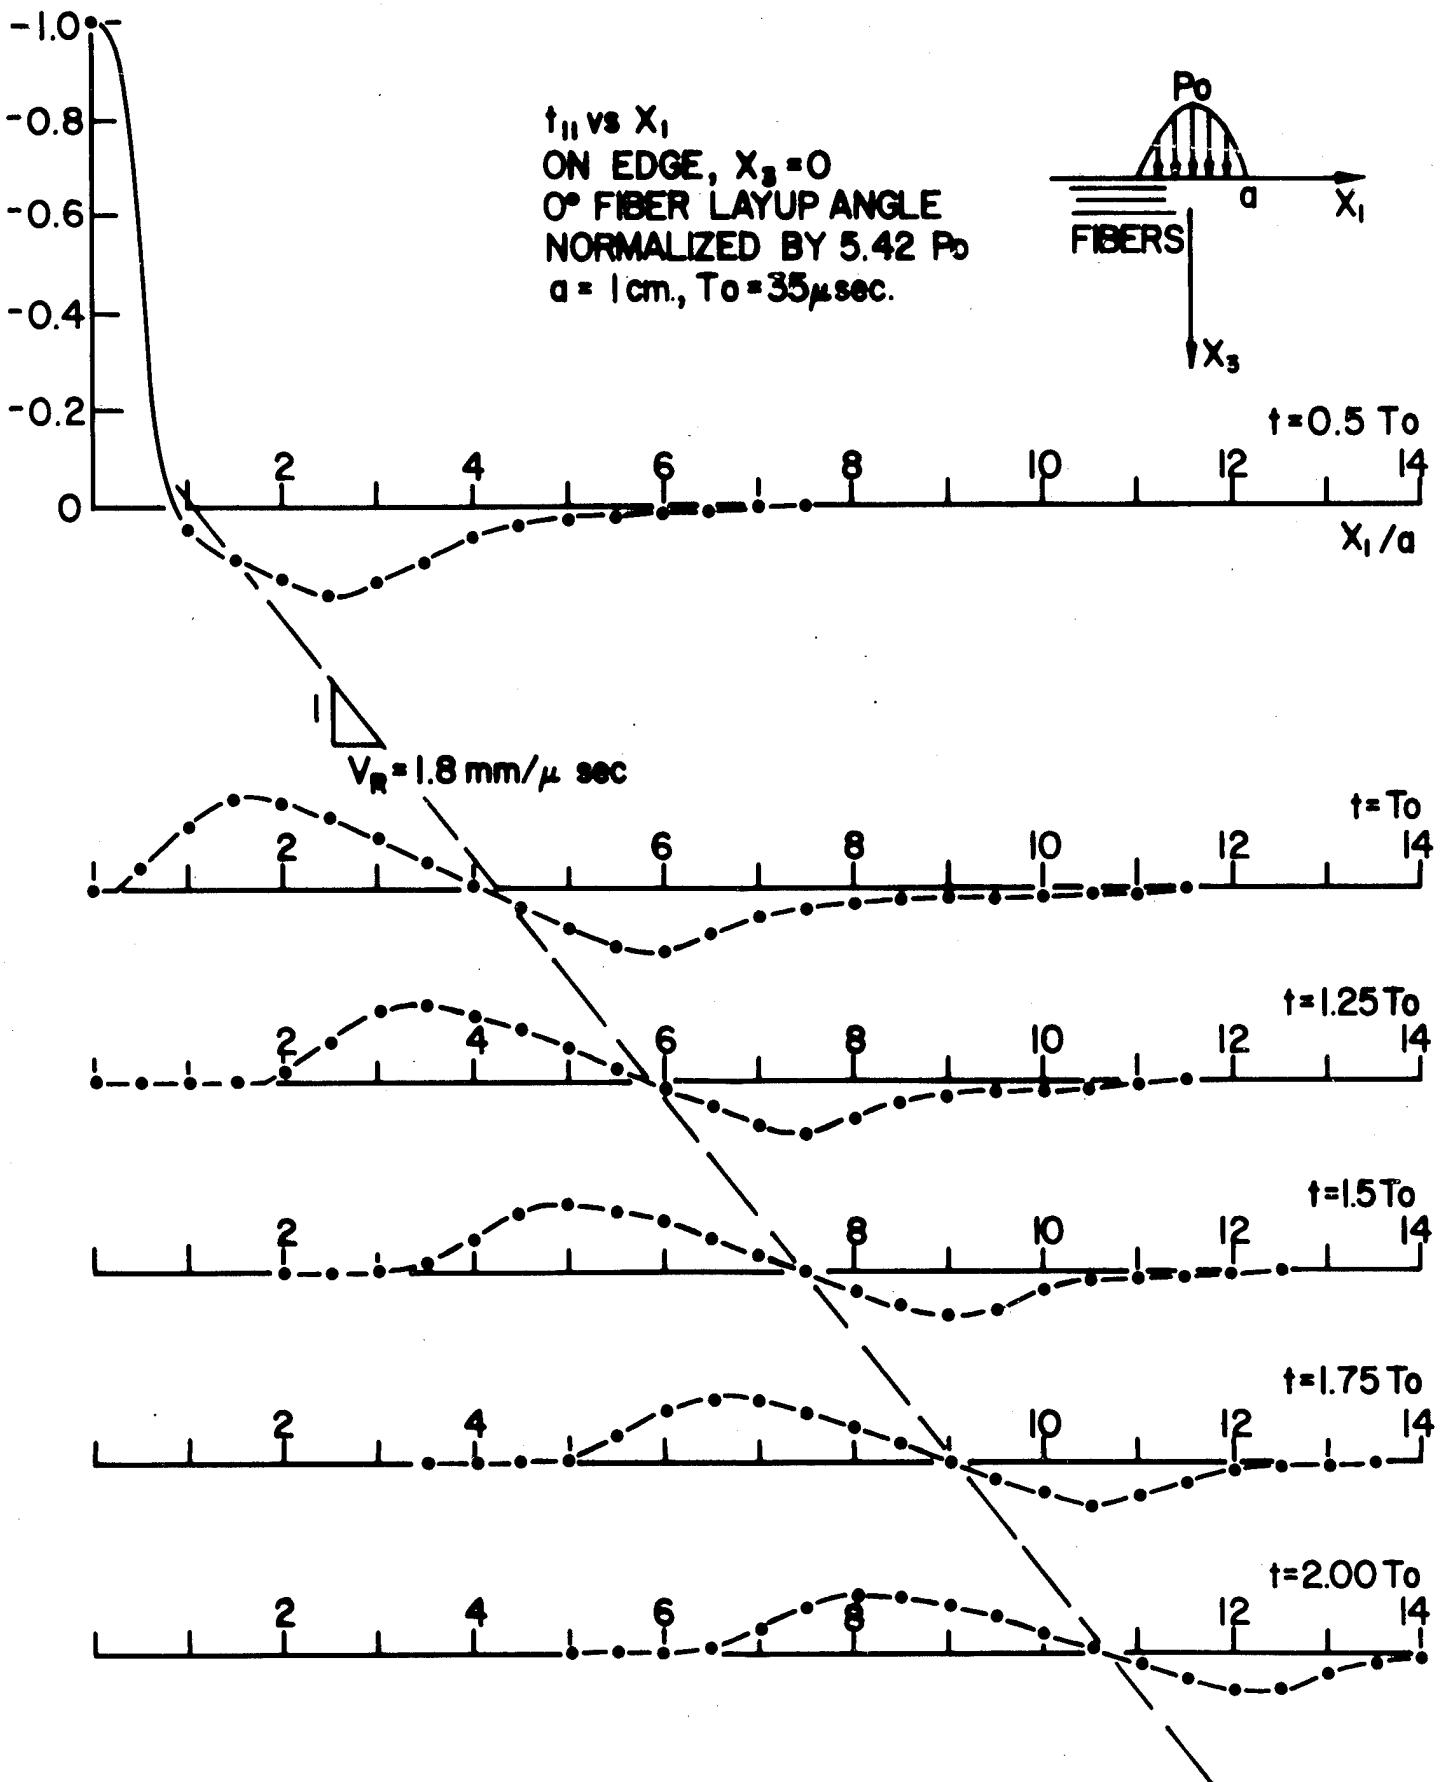

FIGURE 4

Edge Stress t_{11} , Surface Wave for 0° Fiber layup Angle: 55% graphite fiber/epoxy matrix composite

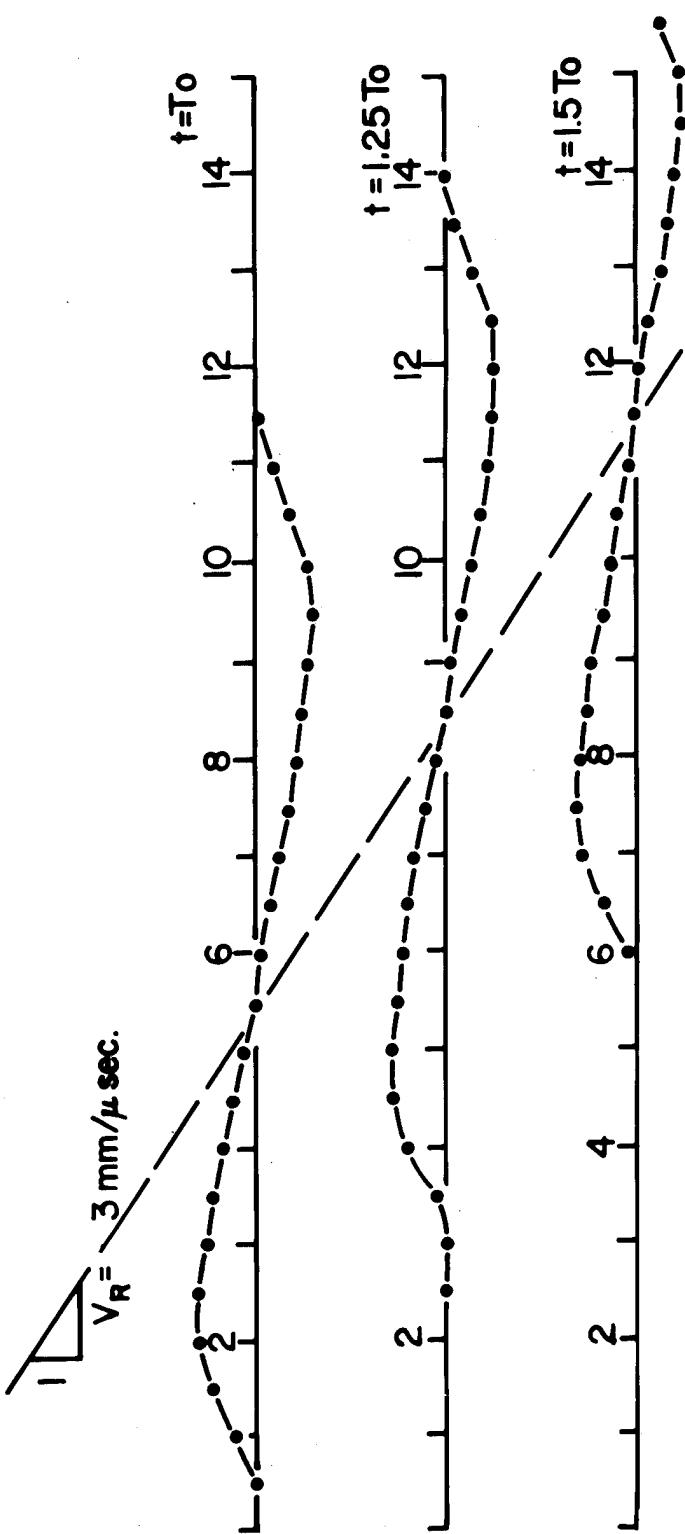

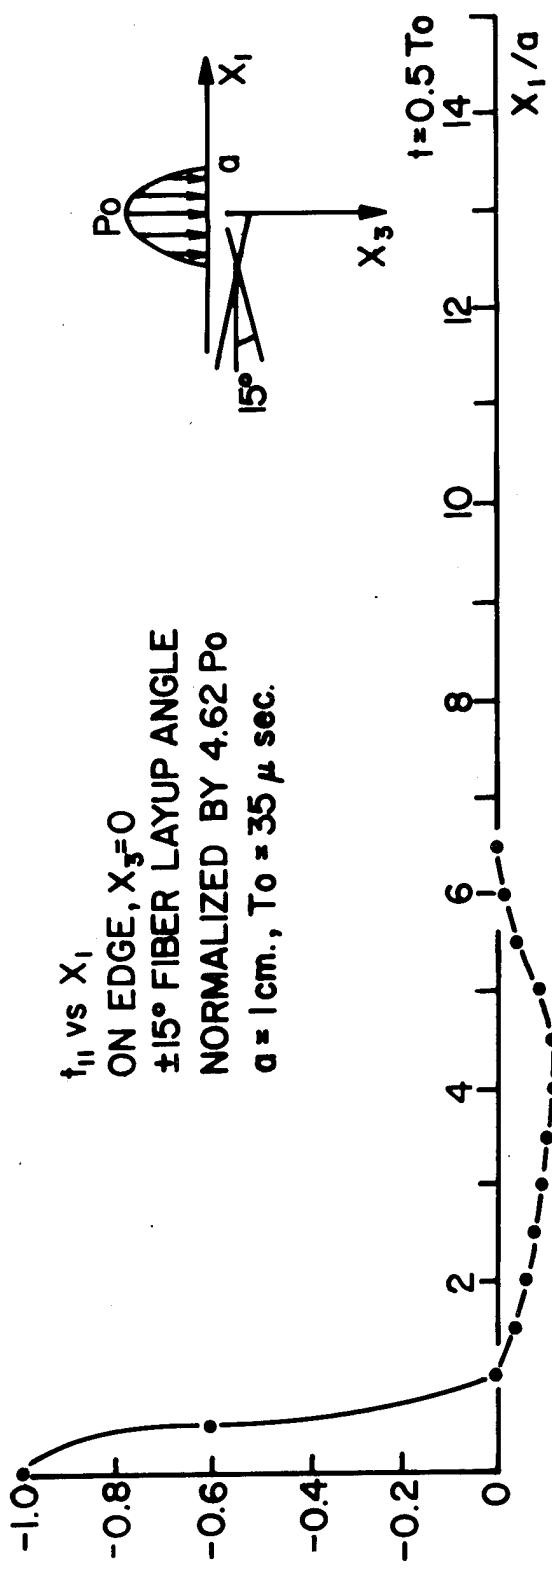

FIGURE 5

Edge Stress t_{11} Surface Wave for $\pm 15^\circ$ Fiber Layup Angle: 55% Graphite fiber/epoxy matrix composite.

STRESS T.33

0.4447

TIME-DT= 0.4366E-05

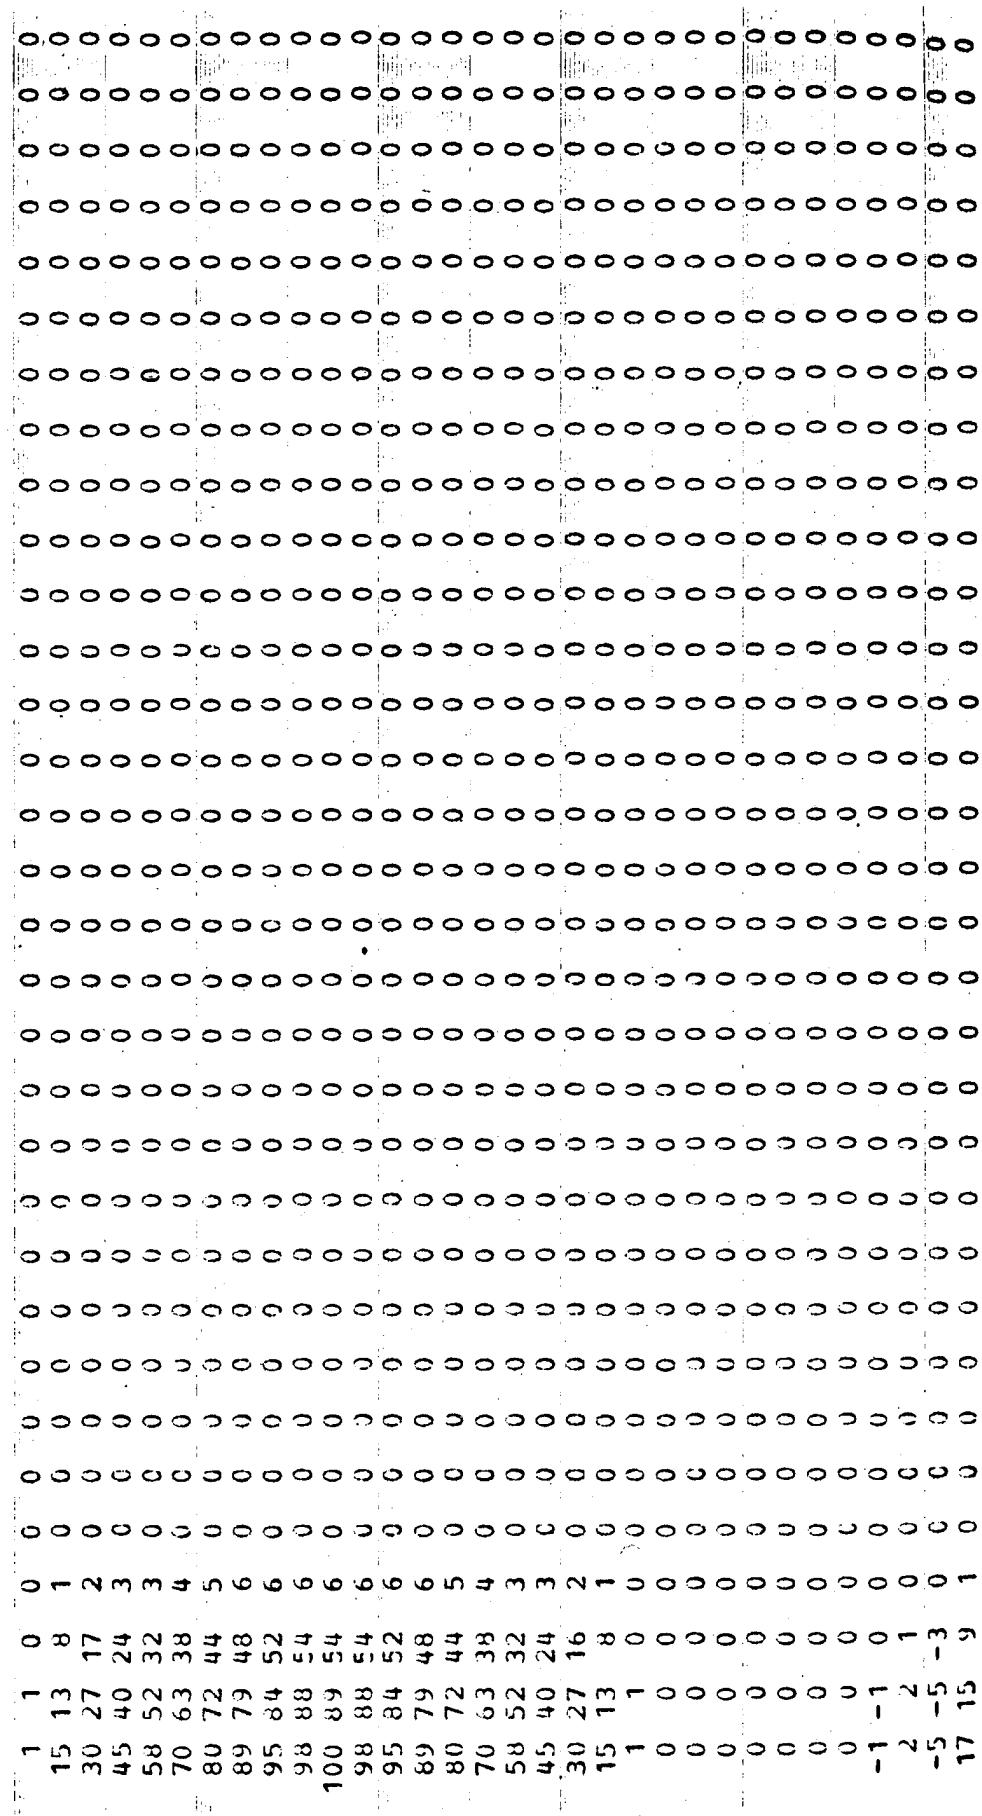

FIGURE 6

Computer Map of Edge Impact Pressure t_{33} Impact Time 87 μ sec.

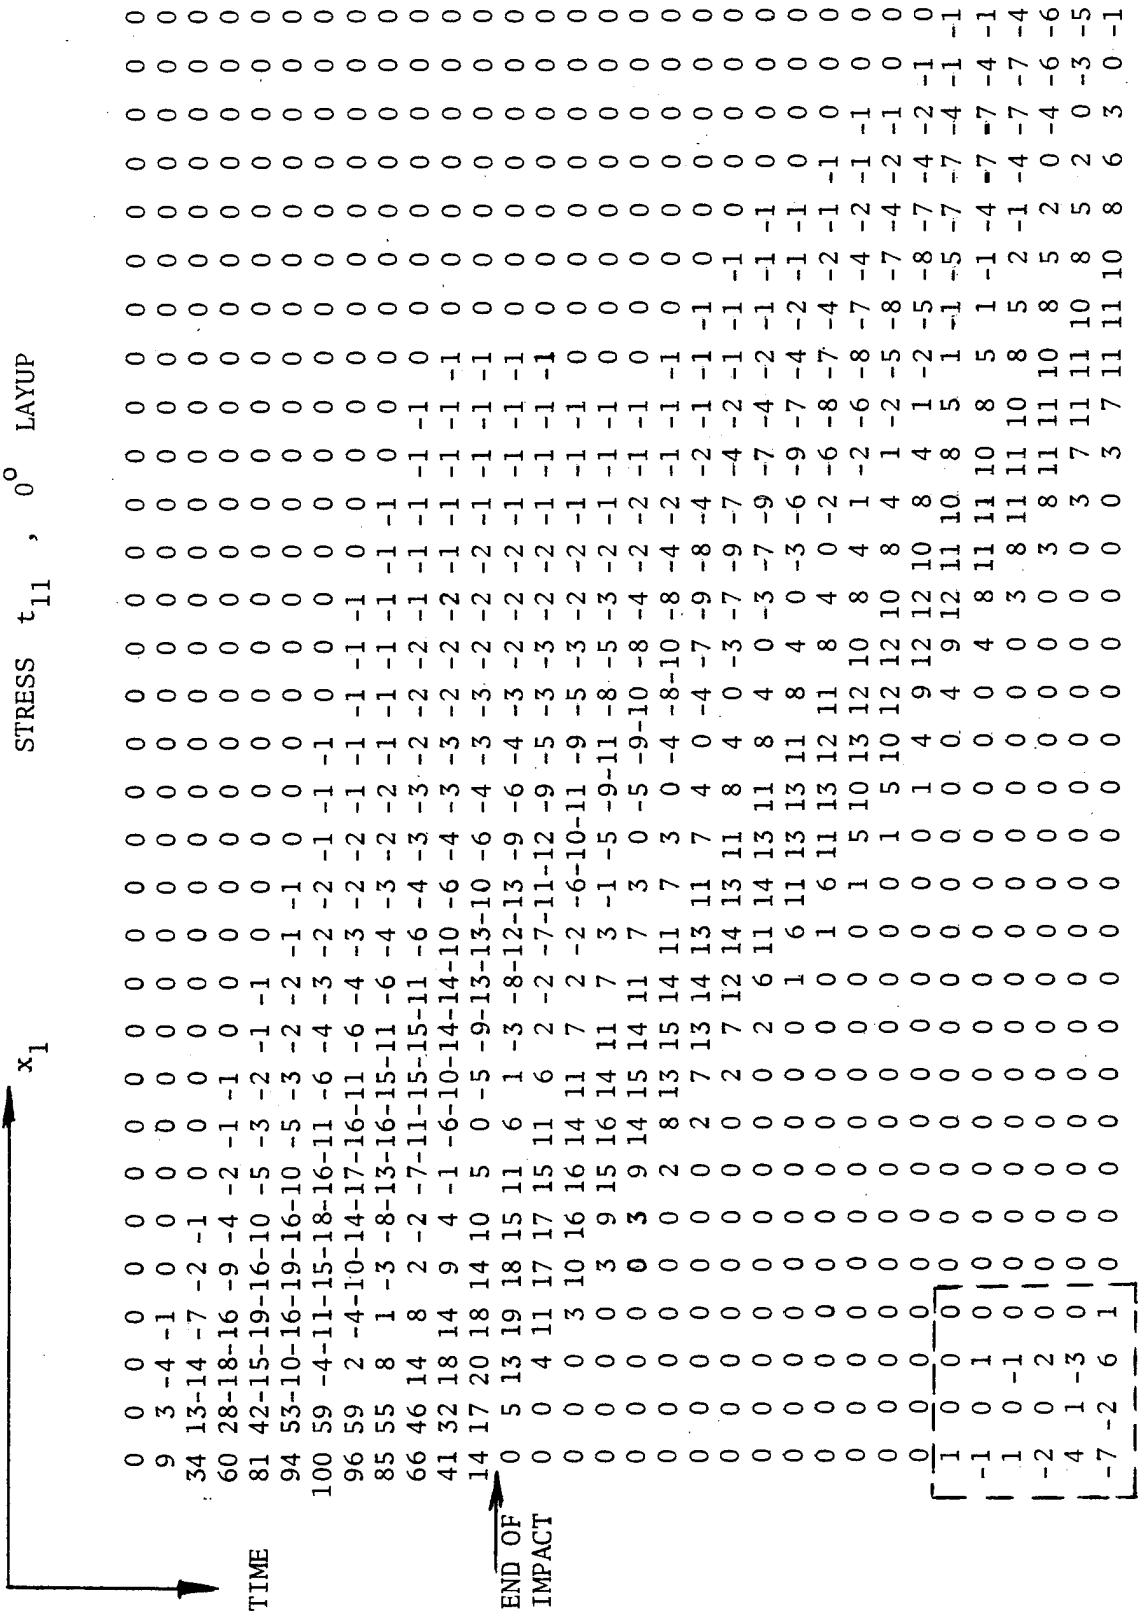

FIGURE 7
Computer Map of Edge Stress t_{11} Surface Wave in the Space-Time (x_1, t) Domain

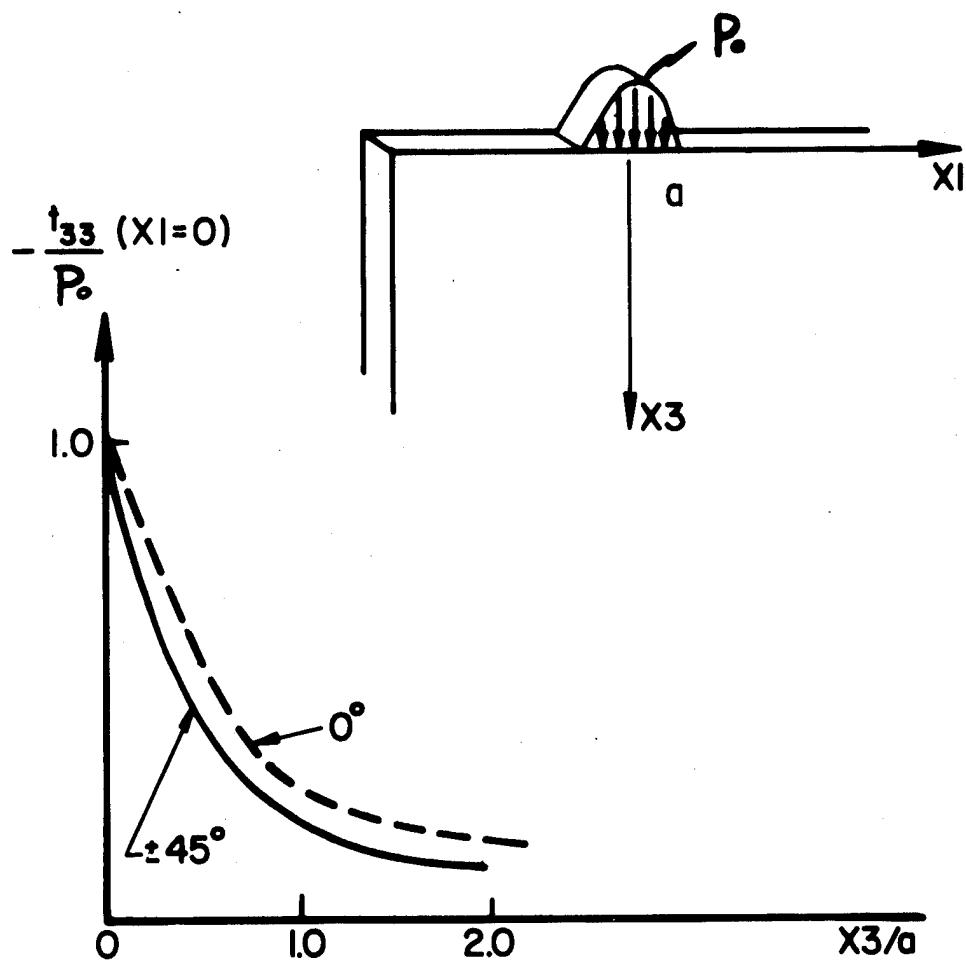

FIGURE 8
Decrease of Stress t_{33} with Distance from the Impact Edge.

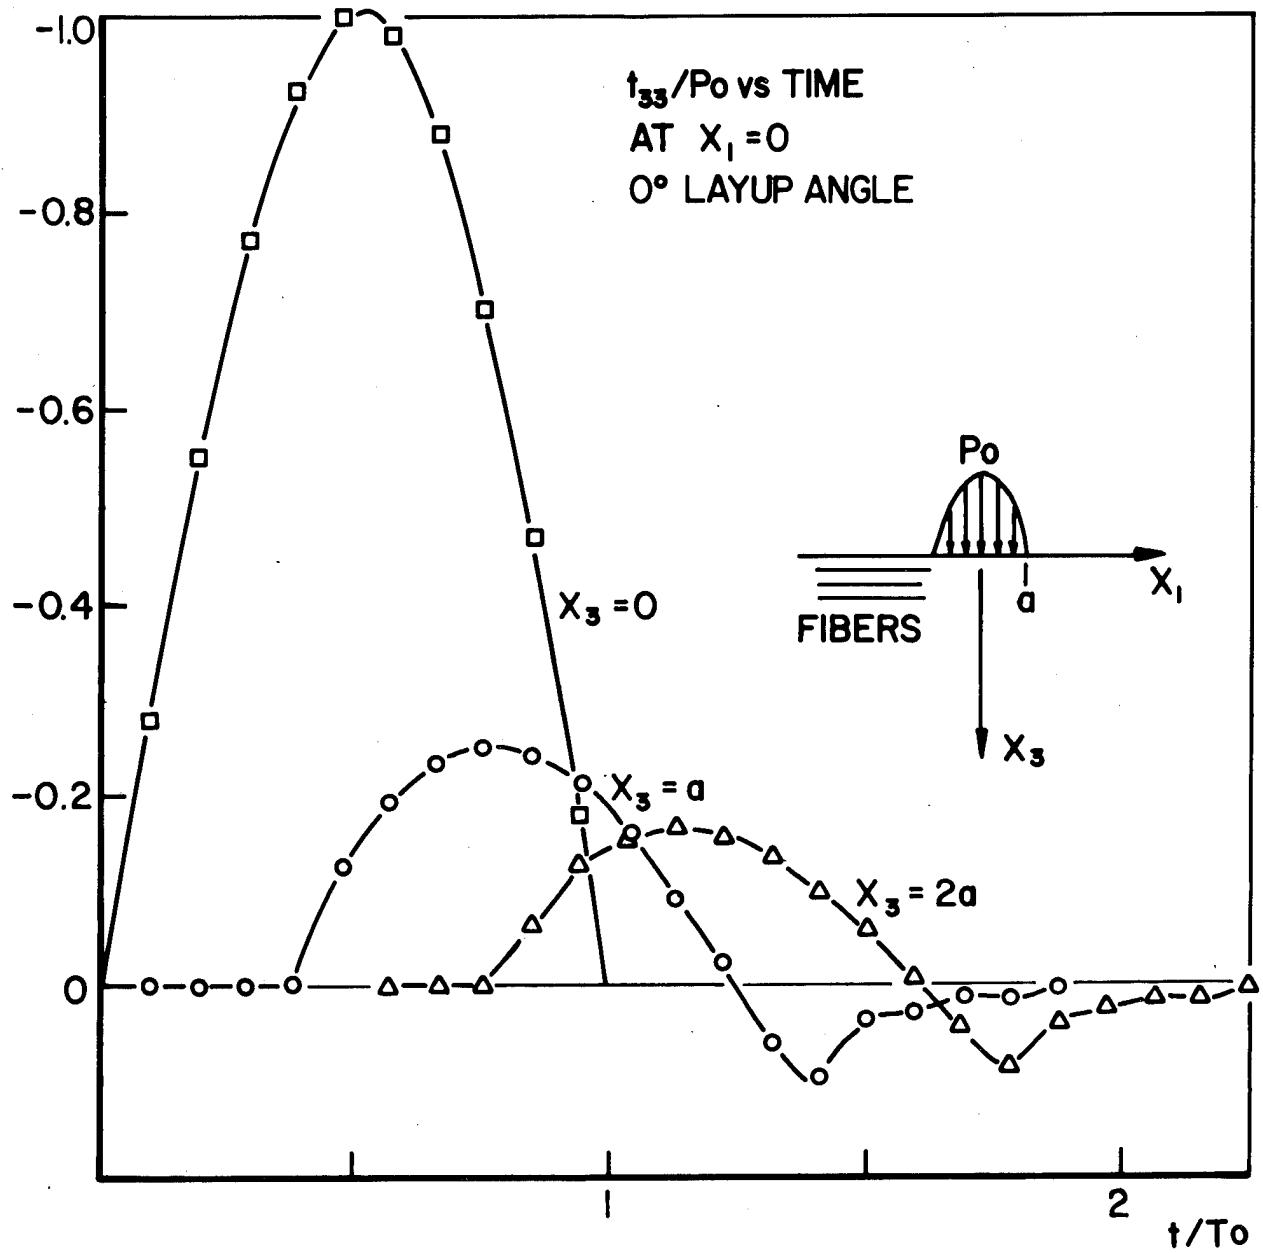

FIGURE 9

Stress t_{33} versus Time at Different Distances from the Edge under the Contact Point.

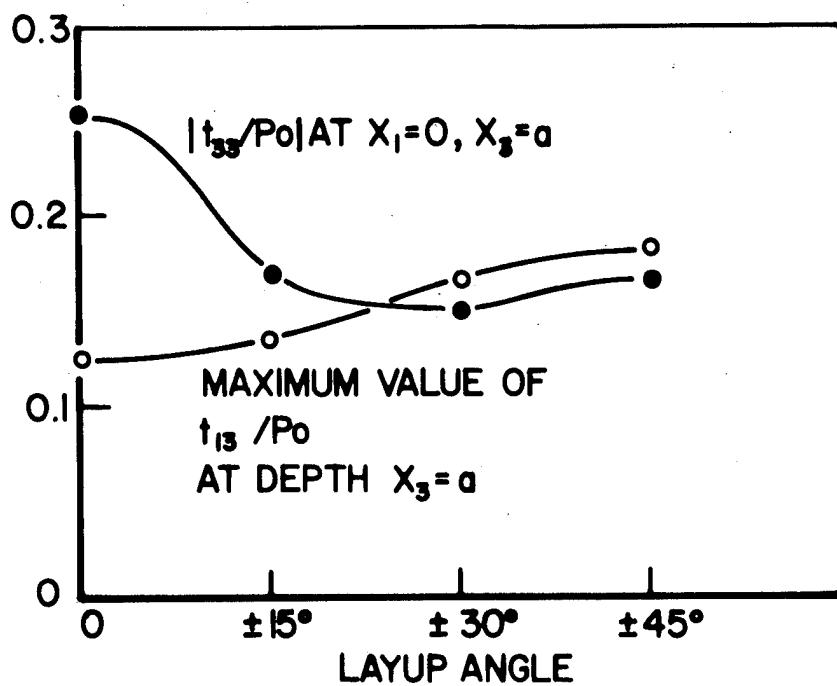

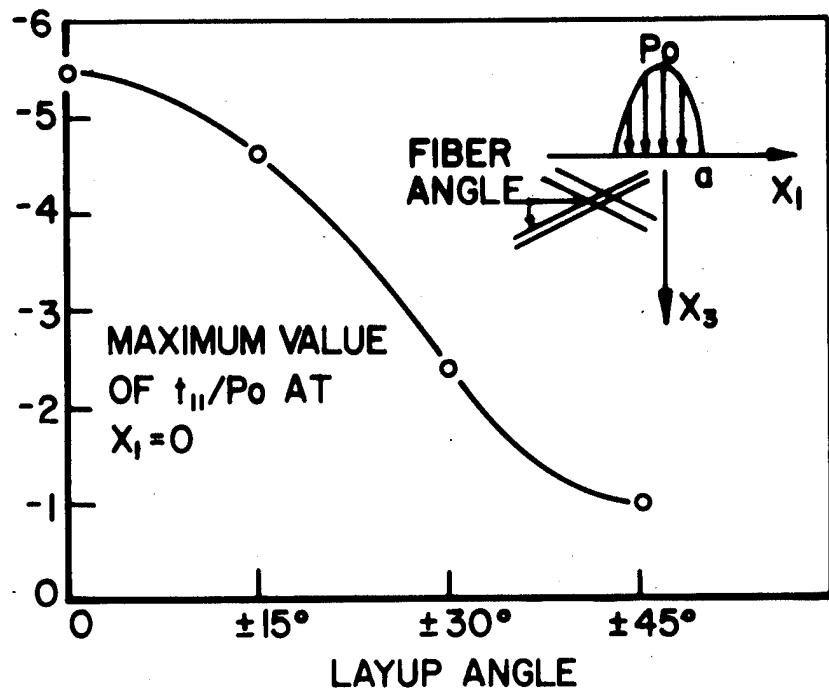

FIGURE 10

Maximum Stresses versus Layup angle for 55% Graphite Fiber/epoxy Matrix Composite.

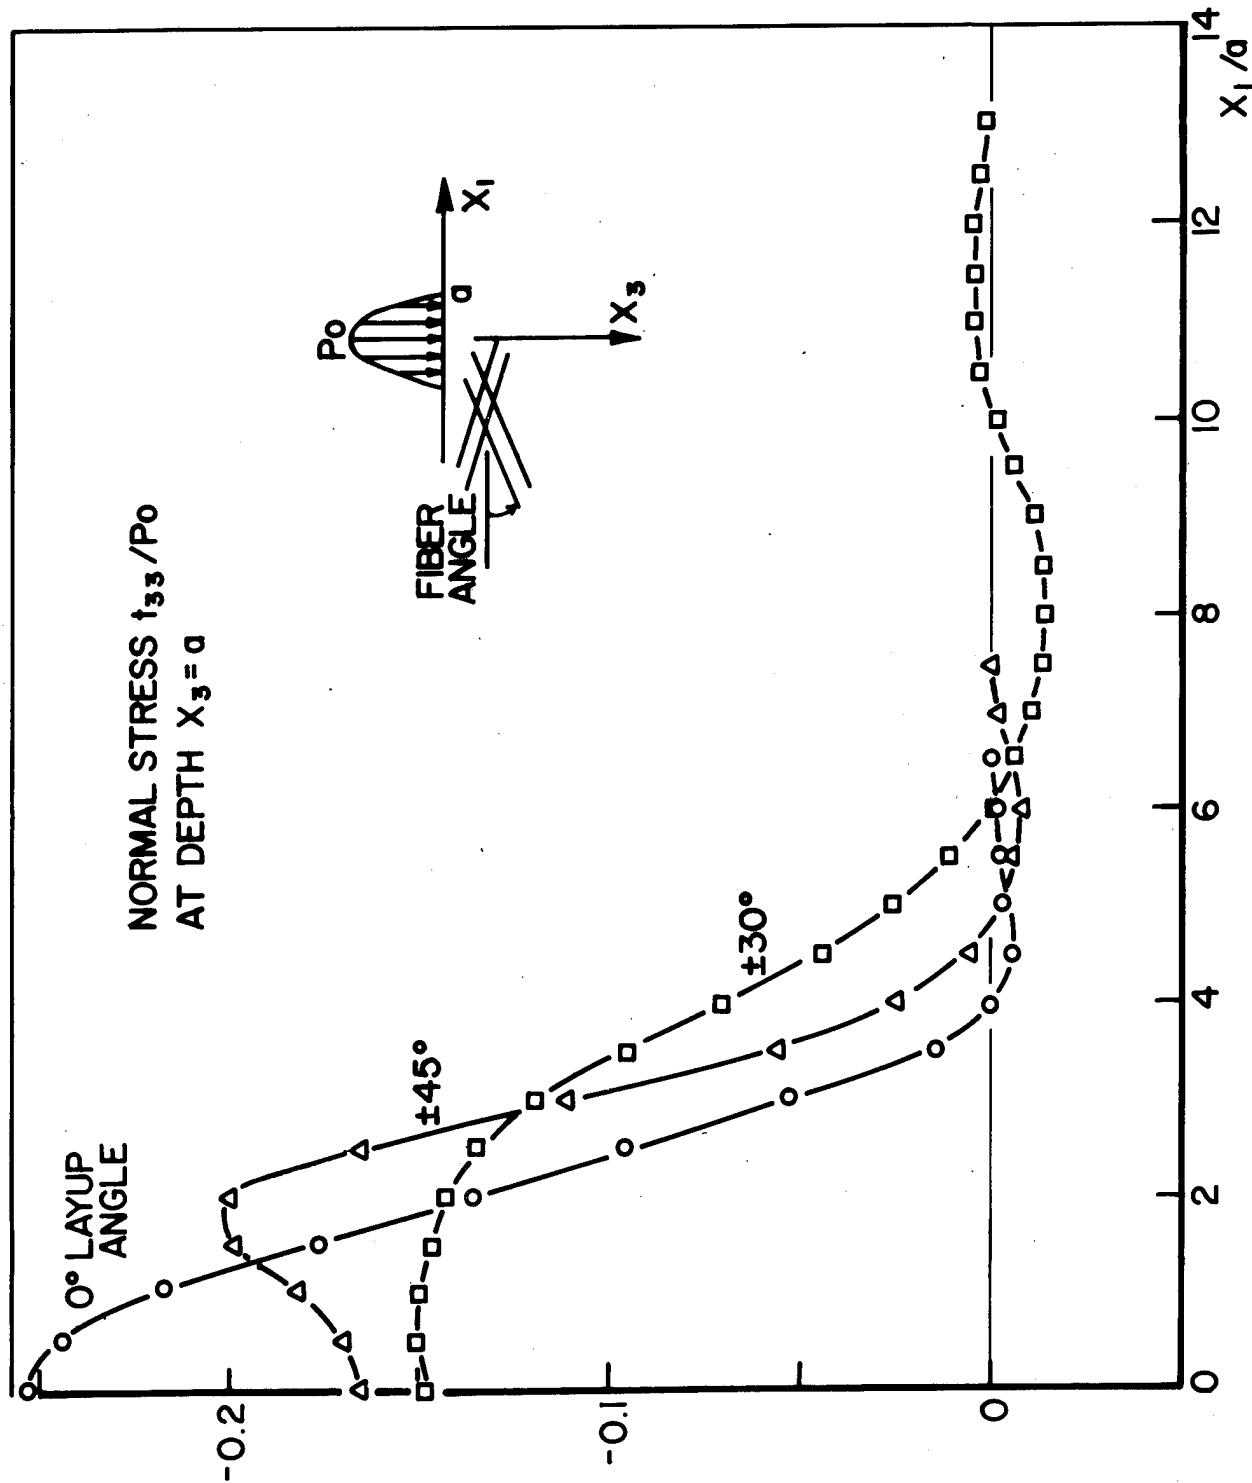

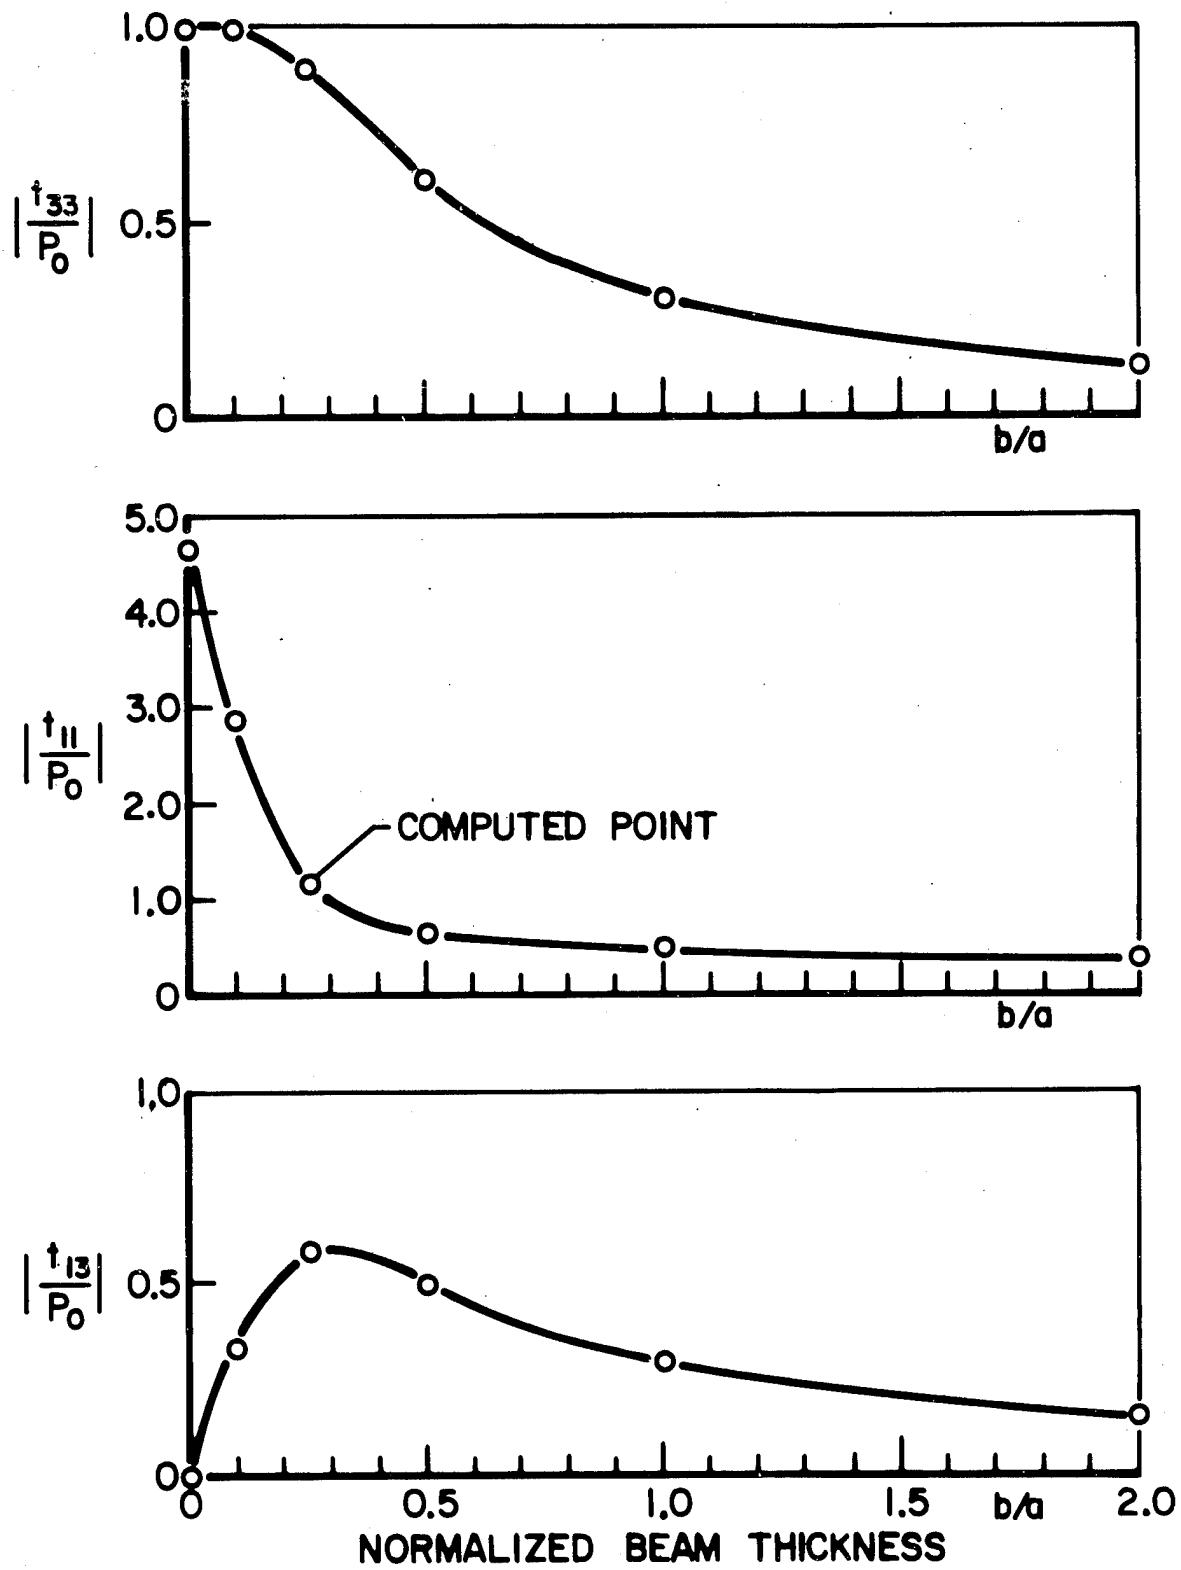

FIGURE 11

Distribution of Stress t_{33} Along the Edge for Fiber Layup angles 0° , $\pm 30^\circ$, $\pm 45^\circ$.

NORMALIZED STRESSES IN COMPOSITE
AT STRIP-EDGE INTERFACE

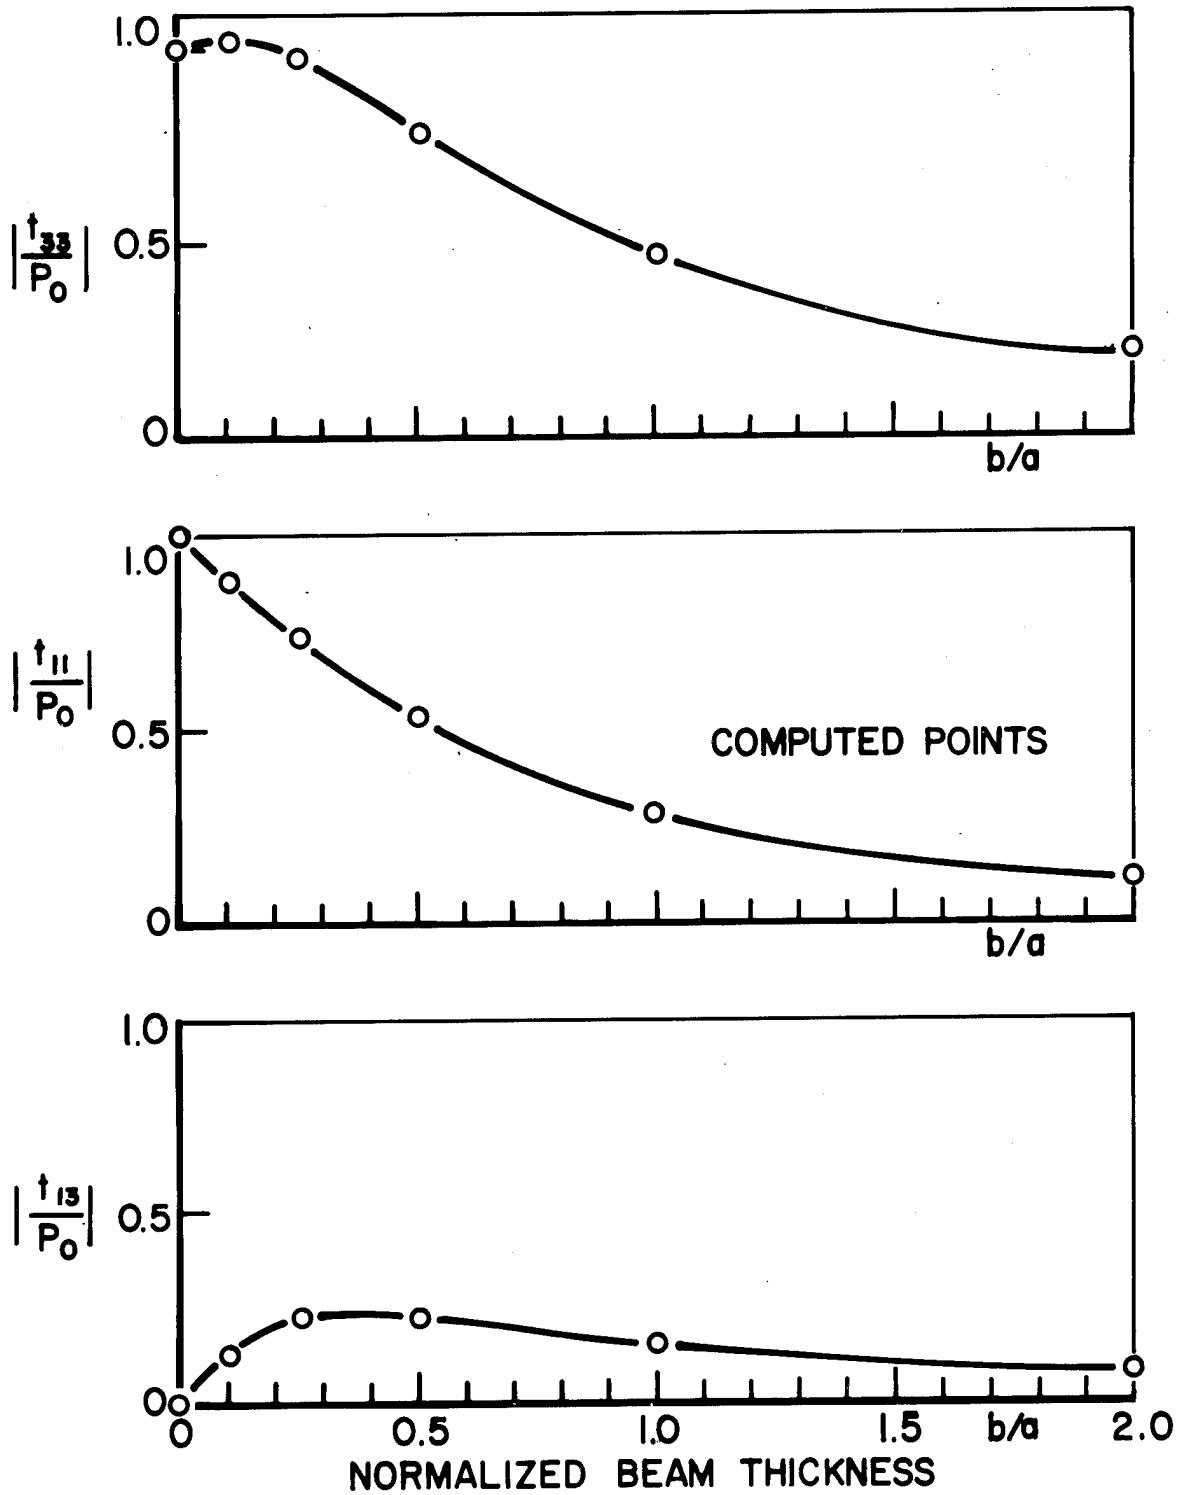

DATA FOR 55% GRAPHITE FIBER/EPOXY MATRIX
 $\pm 15^\circ$ LAYUP - STEEL STRIP

FIGURE 12a

Effect of Edge Strip Thickness on Interface Stresses.

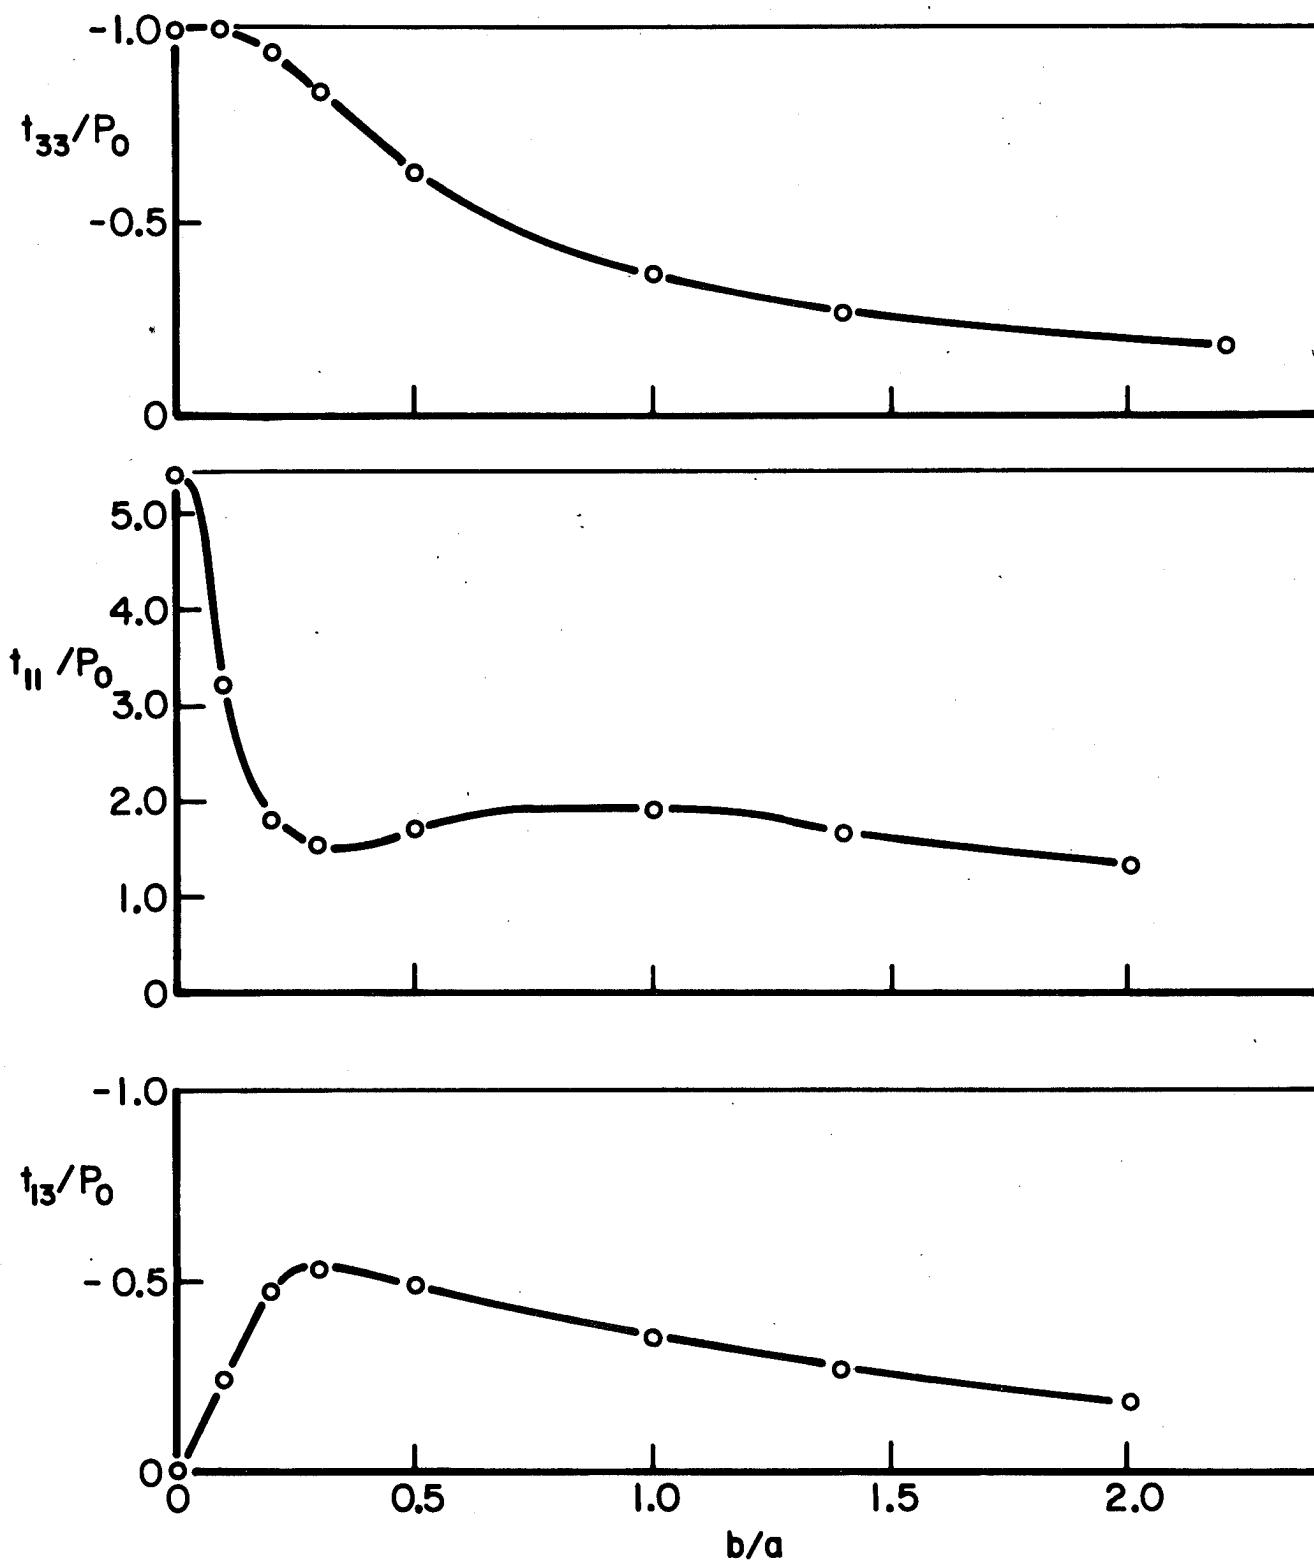

NORMALIZED STRESSES IN COMPOSITE
AT STRIP - EDGE INTERFACE

DATA FOR 55% GRAPHITE FIBER/EPOXY MATRIX
 $\pm 45^\circ$ LAYUP ANGLE - STEEL STRIP

FIGURE 12b

Effect of Edge Strip Thickness on Interface Stresses.

0° LAYUP ANGLE ALUMINUM STRIP

$X_3 = 0$, $a = 1\text{ cm}$, $T_0 = 35\mu\text{sec}$

FIGURE 13

Effect of Edge Strip Thickness on Interface Stresses.

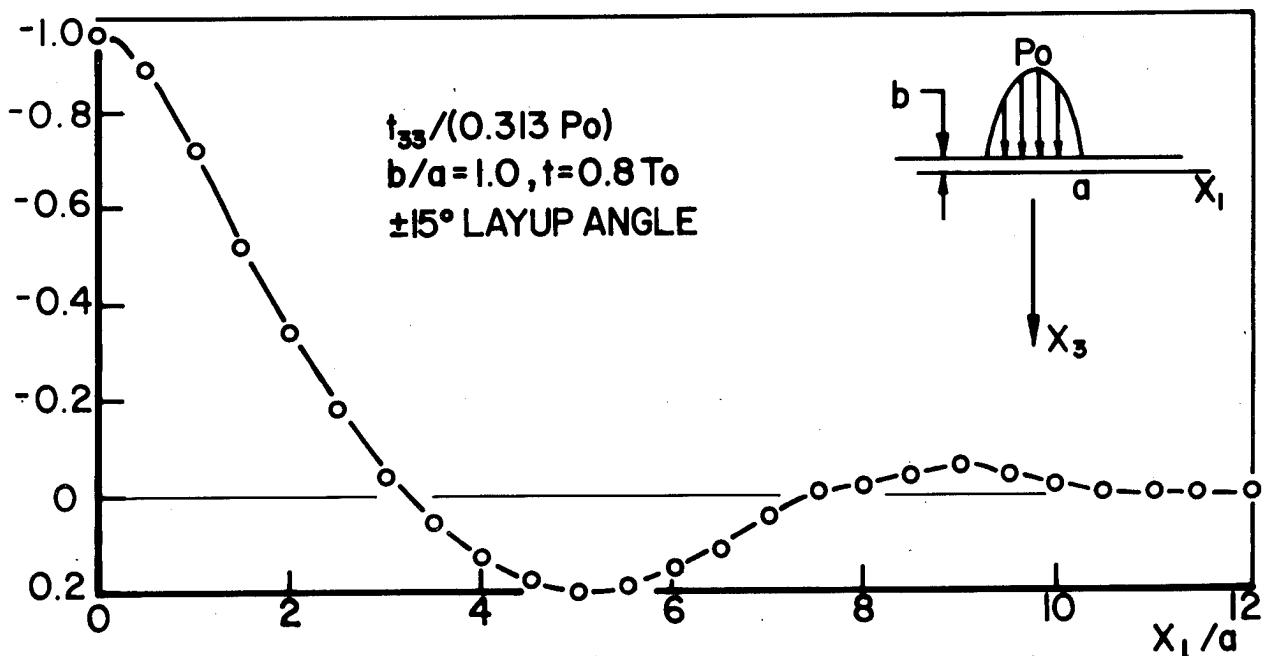

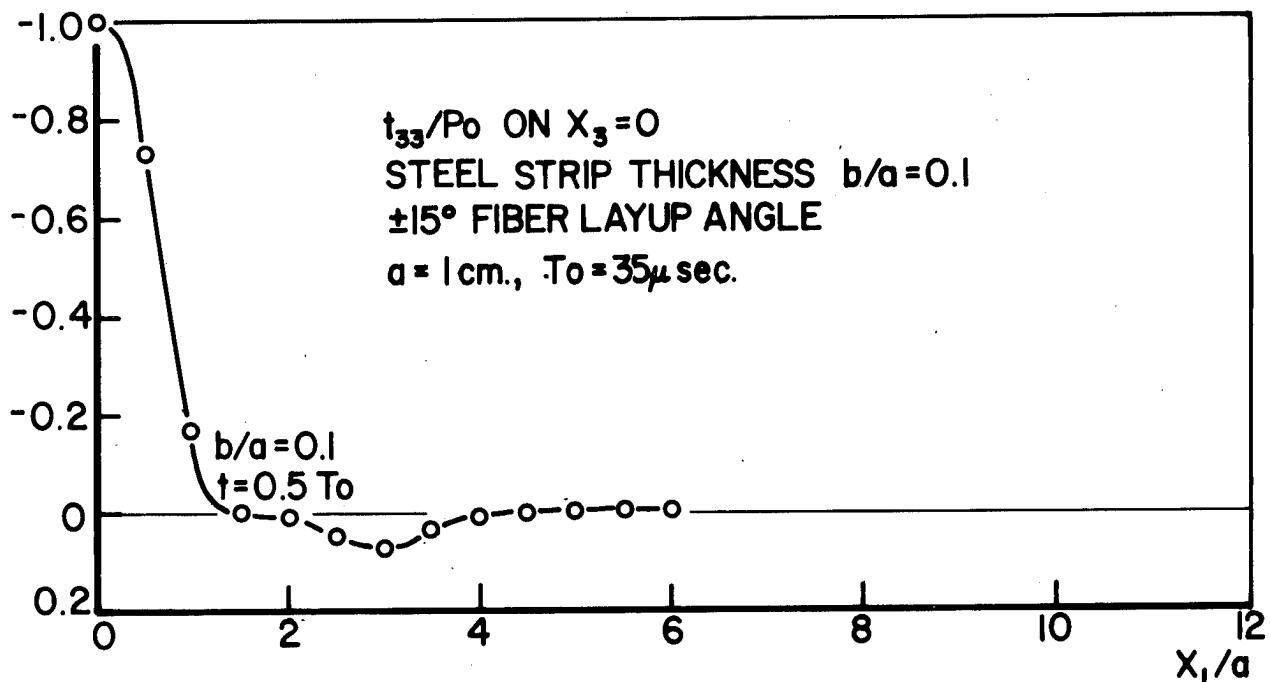

FIGURE 14
 Effect of Edge Strip Thickness on Stress t_{33} Distribution Along the Edge.

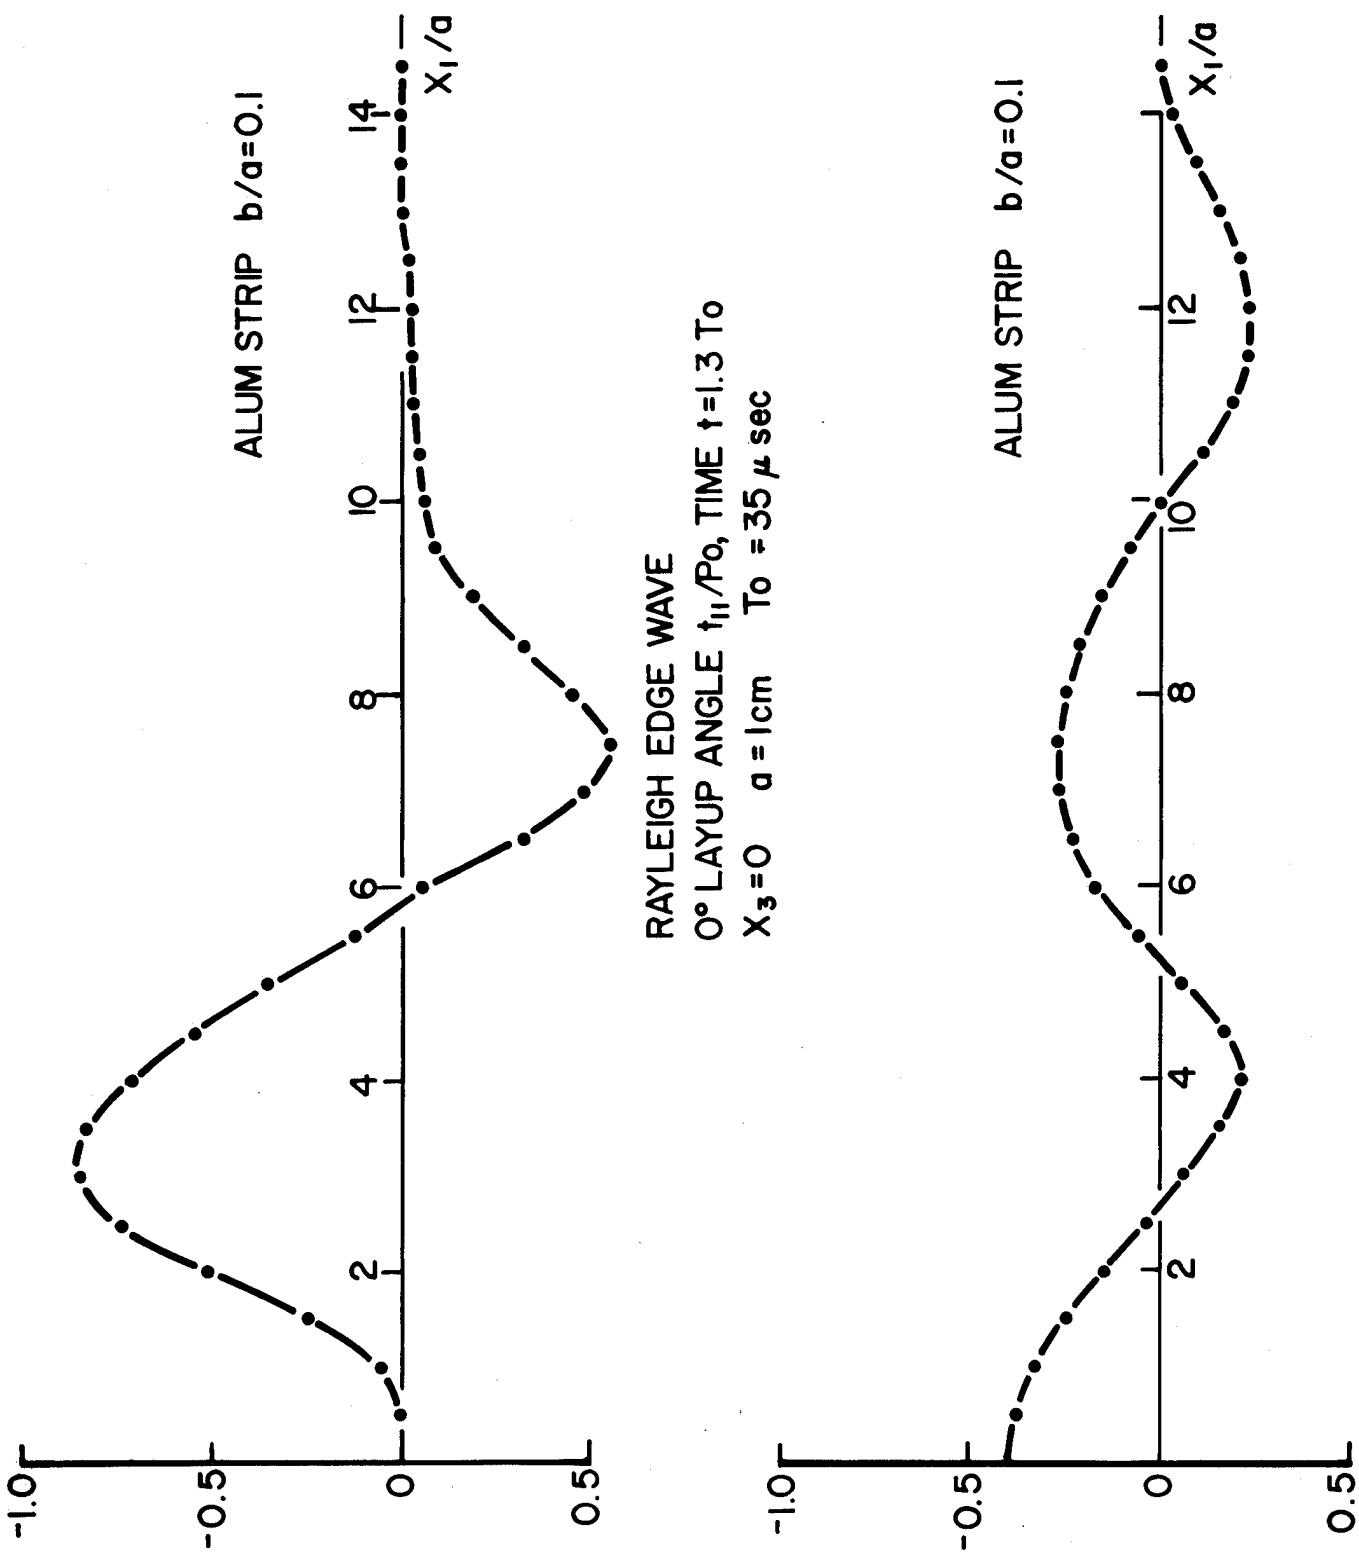

FIGURE 15
Effect of Edge Strip Thickness on the Rayleigh Edge Wave Shape.

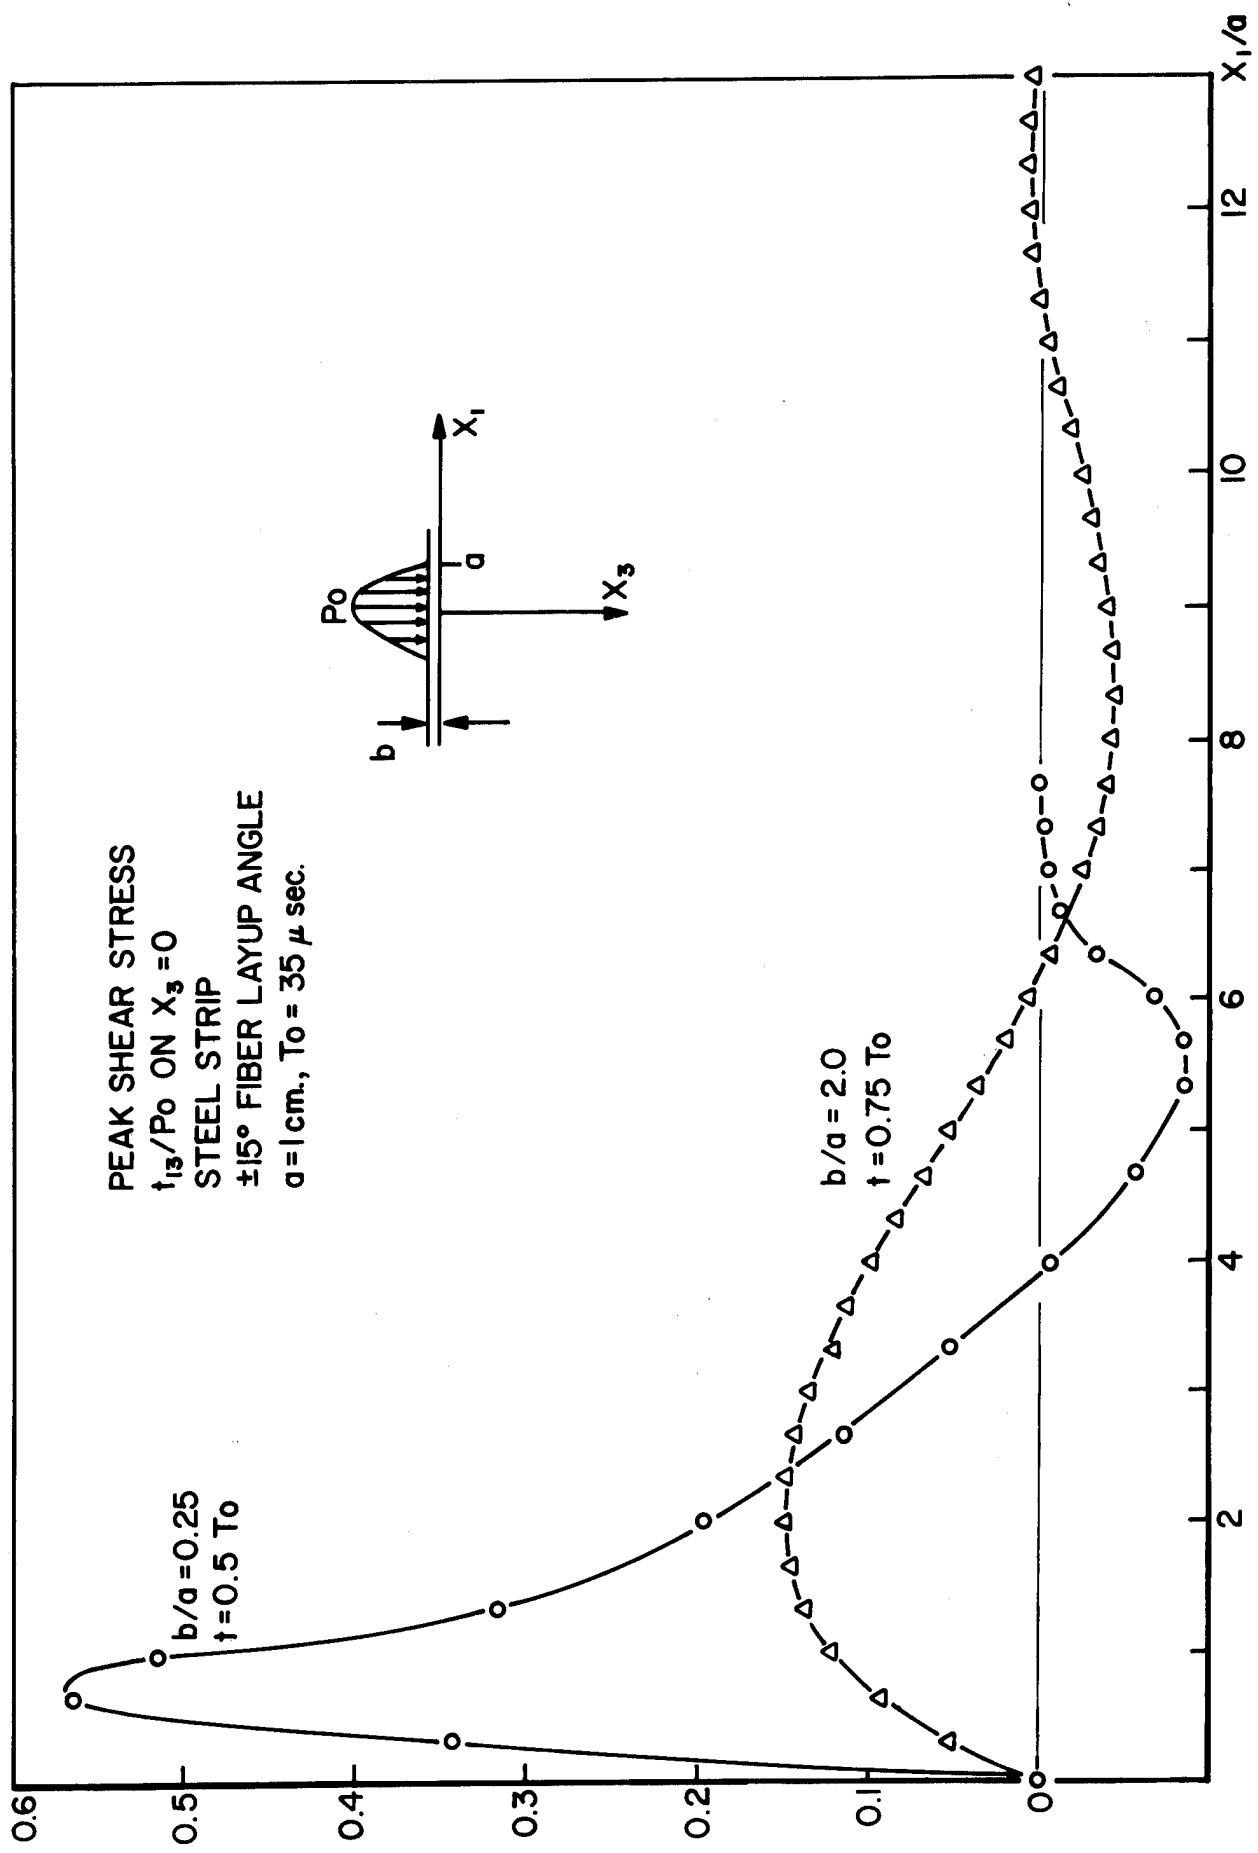

FIGURE 16
 Effect of Edge Strip Thickness of Interface Shear Stress t_{13}
 Distribution Along the Edge.
